THE

British Medical Journal.

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION.

EDITED BY

NORMAN GERALD HORNER, M.A., M.D.

VOLUME I, 1933

JANUARY TO JUNE

London:
PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION,
TAVISTOCK SQUARE, LONDON, W.C.1.

KEY TO DATES AND PAGES

THE following table, giving a key to the dates of issue and the page numbers of the BRITISH MEDICAL JOURNAL and SUPPLEMENT in the first volume for 1933, may prove convenient to readers in search of a reference.

Serial No.	Date of Issue.	Journal Pages.	Supplement Pages.
3757	Jan. 7th	1 – 46	1 – 8
3758	,, 14th	47 – 86	9 – 12
3759	,, 21st	87 – 128	13 – 20
3760	,, 28th	129 – 172	21 – 28
3761	Feb. 4th	173 – 212	29 – 40
3762	,, 11th	213 – 256	41 – 48
3763	,, 18th	257 – 300	49 – 56
3764	,, 25th	301 – 352	57 – 68
3765	Mar. 4th	353 – 398	69 – 84
3766	,, 11th	399 – 442	85 – 92
3767	,, 18th	443 – 498	93 – 100
3768	,, 25th	499 – 548	101 – 112
3769	April 1st	549 – 596	113 – 124
3770	,, 8th	597 – 640	125 – 132
3771	,, 15th	641 – 684	133 – 140
3772	,, 22nd	685 – 730	141 – 152
3773	,, 29th	731 – 770	153 – 192
3774	May 6th	771 – 810	193 – 212
3775	,, 13th	811 – 858	—
3776	,, 20th	859 – 904	213 – 228
3777	,, 27th	905 – 948	229 – 236
3778	June 3rd	949 – 992	237 – 248
3779	,, 10th	993 – 1032	249 – 260
3780	,, 17th	1033 – 1090	261 – 276
3781	,, 24th	1091 – 1138	277 – 296

INDEX TO VOLUME I FOR 1933

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma, Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Light, Roentgen, Radium, X Rays; Status Lymphaticus and Thymus; Eye, Ophthalmia, and Vision; Pyelography and Urography; Lunacy and Mental Diseases; Sunlight and Ultra violet; Bicycle and Cycle; Motor and Automobile; Association, Institution, and Society, etc. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Reviews," etc. Original Articles are indicated by the letter (O).

A.

ABBOTT, Charles Clement, committed for trial for manslaughter, 541—Acquittal of, 677
Abdominal aorta. *See* Aorta
Abdominal cavity, dead foetus in, rupture of previous Caesarean section (Irene P. Rowlands), 100
Abdominal musculature, non-differentiation of, 1032
Abdominal palpation in the "dangle" position (C. Jennings Marshall), 413—Correspondence on, 455 *See also* Palpation
Abdominal retractor. *See* Retractor
Abdominal surgery. *See* Surgery
Abdomino-perineal operation, 932
ABERCROMBIE, R. G.: Transitory arthritis of the hip in children, 1125
ABERCROMBIE, Robert H.: The G.P. and midwifery, 1072
Aberdeen. *See* Scotland
Ability, review of book on, 192
Abortion, statistics of (Raymond Pearl), 576
Abortus fever in Dorset (H. R. Unwin), 901
ABRAHAMSON, L.: Bilateral spontaneous pneumothorax, 273
Abscess, alveolar, treatment of, 242, 340, 398
Abscess of breast, treatment of (Hamilton Bailey), 1061 (O)—Correspondence on, 1129
Abscess, perinephric: rupture of followed by general peritonitis (J. J. Jennings), 61
Abscess of thigh, 223
Abscesses, intermuscular, with special reference to abscesses of thigh (H. A. Phillips), 225 (O)
ABT, I. A. (and A. F. ABT): *Pediatrics*, rev., 520
Academic Assistance Council, 974, 1114—Aid for displaced German professors, 974—Leading article, 1114
Academy, the Royal, 795

ACADEMY, ROYAL, OF MEDICINE IN IRELAND: Election of Honorary Fellows, 1055
Section of Laryngology and Otology.—Facio-hypoglossal anastomosis, 725—Mastoiditis, 727
Section of Medicine.—Bilateral spontaneous pneumothorax, 273—Pernicious anaemia without achlorhydria, 516—Coeliac disease, 827
Section of Obstetrics.—Placenta accreta, 369—Pituitary extract in labour, 370
Section of Pathology.—Mediterranean fever, 147—Chorion-epithelioma of Fallopian tube, 370—Zondek-Aschheim test for pregnancy, 659
Section of Surgery.—Premedication with nembutal, 15—Acute tetanus, 230—Fracture of femoral neck, 747—Surgery of facial paralysis, 1003

Accident and disease in Workmen's Compensation (leading article), 621
Accident, motor-car, doctor injured in (Goldfoot v. Brewer), 1133
Accident proneness, report on (E. Farmer, E. G. Chambers, and F. J. Kirk), 1116
Accidents, neuropsychiatric, complicating antirabic treatment (G. Stuart and K. S. Krikorian), 501 (O)
Accidents, road: In the last five years (parliamentary note), 350—Causes of (parliamentary note), 410—Compensation for (parliamentary note), 439—And the driving test (parliamentary note), 851—In the metropolitan area (parliamentary note), 852—Payment of remuneration to registered medical practitioners and hospitals for treatment to persons injured in use of motor vehicles on roads (parliamentary note), 933. *See also* Road Traffic Bill *and* Road Traffic Emergency Treatment Bill
"Acetone and diacetic acid" in urine, 486, 581. *See also* Urine
Acetylcholine in treatment [illegible] ...psy (F. L. ... d), 933 (O)
... 737
... (Charles H. Menand), 220 (O)
ACLAND, Hugh Thomas Dyke, knighthood conferred on, 1015, 1020
Acne vulgaris, a symptom, not a disease (P. B. Mumford), 143 (O)—Correspondence on, 248
Acta Radiologica Supplementum XV: A Study of the Ionization Method for Measuring the Intensity and Absorption of Roentgen Rays, and of Efficiency of Different Filters Used in Therapy (Robert Thoraeus), 74
ADAM, James: Hospitals, infection and asthma, 121—Treatment of chronic suppurative otitis, 527
ADAMS, A.: Diagnosis of early phthisis, 142
ADAMS, A. Wilfrid: Correspondence, 523—British Hospitals for Foreigners, 677

Pancreas, Pseudocyst of the (D. J. Harries)	655
Parkin, Alfred	293
Peptic Ulcer, Surgical Treatment of (D. P. D. Wilkie)	773
Phlebotomist's Carrier	233
Prostate, Perurethral Operations on the (Kenneth Walker) ...	356
Radium Applicator for Vaginal Use	922
Sargent, Sir Percy	167
Scalp, Total Avulsion of the: A New Method of Restoration (G. F. Mitchell)	14
Scotoma Protractor	1112
Soudamore, Charles George Collins	1131
Skull Defects Repaired by a New Pedicle Bone-Graft Operation (R. Watson Jones)	780
Smith, Joseph Priestley	850
Syringe Case	104
Syringe, Insulin	465
Table, Tilting, for Hip Operations in Children	618
Taylor, Sir William...	251
Towel for Suprapubic Prostatectomy	277
Tuberculin Test [Cutaneous] Instrument (W. S. Craig)	184
Tuberculosis, Pulmonary, Chronic (R. C. Wingfield)	181
Vagina, Congenital Absence of the (Norman Hodgson)	822
Whitelegge, Sir Benjamin Arthur	806
X-Ray Apparatus, Mobile	923

EPITOME

OF

Current Medical Literature.

JANUARY TO JUNE, 1933

London:

PRINTED AND PUBLISHED AT THE OFFICE OF THE BRITISH MEDICAL ASSOCIATION, TAVISTOCK SQUARE, LONDON, W.C.1.

INDEX TO THE EPITOME FOR VOLUME I, 1933

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

A.

Abdomen, acute, diagnostic percussion in, 145
Abdomen, blood in, detection of, 16
Abdominal diseases, bacteriological researches in, 252
Abortion, tubal, diagnosis of, 214
Abortions, frequency and mortality of, 248
Abscess, perinephric, 163
Acetylcholine in post-traumatic ankylosis and arthritis, 425
Achlorhydric anaemia. *See* Anaemia
Acid-fastness, differences in the property of, 253
Actinomyces in the mouth, incidence of, 175
Acute abdomen. *See* Abdomen
Addison's disease complicating pregnancy, 153
Addison's disease, vocal symptoms in, 407
ALBERT, F.: Experimental obliteration of the arteries, 157
ALBRONDA, J.: Cerebral symptoms in Weil's disease, 93
Albuminuria in pregnancy, 135
Alcohol as a cause of death, 218
Alcohol, blood, estimation of in drunkenness, 436
Alcoholism, experimental, in normal pregnancy, 113
ALDRICH, R. H.: Infection in burns, 403
Alkalosis complicating the alkaline treatment of peptic ulcers, 131
ALLEN, E. V.: [illegible] control of polycythaemia vera b[illegible] brain, 240
ALLEN, S. S.: Cysticer[illegible]
Allergy, food, evaporated milk in, and infant feeding, 26
Allergy, food, gastro-intestinal, x-ray study of, 422
ALS-NIELSEN: Lumbar anaesthesia with tropacocaine, 212
Ambulatory fractures. *See* Fractures
Amnesia in childbirth, 213
AMOIA, R.: *Trichomonas vaginalis* in the male urethra, 56
Amytal and ephedrine in asthma, 262
Anaemia, achlorhydric, simple, 158
Anaemia achylica simplex of Faber, 233
Anaemia, pernicious, stomach of hog in, 187
Anaemia, pernicious, liver extract infections in, 8
Anaemia, pernicious, spinal symptoms in, treatment of, 331
Anaesthesia, avertin: The present status of, 64—In childbirth, 213—General, 298—In midwifery, 336
Anaesthesia, endobronchial, closed, 65
[illegible] with avertin, 298
[illegible] th tropacocaine, 212
[illegible] —Respiratory and circu- 66
[illegible] idehyde as a, 210
Anaesthetic, [illegible] the, 211
[illegible] low (pantocain), 385
Anaesthetics, [illegible] stration of in New York, 300
[illegible] antigenic value of, 321
[illegible] concentrated, 288
[illegible] gnosis in children with [illegible] erculosis, 414
[illegible] Treatment of cardiac arrhythmias by [illegible] sium salts, 295
Angina, attacks of, arterial blood pressure during, 438
Angina, Ludwig's, sublingual incision in, 150
Angina pectoris, pain in, 307
Angioneurotic oedema and bacterial hypersensitivity, 119
Ankylosis, post-traumatic, acetylcholine in, 425
Antibodies, poliomyelitic, in normal adult serums, 421
Anti-gas-gangrene serums, standardization of, 54. *See also* Serums
Antistreptolysin and streptococcal antitoxin, relation between, 452
Antitoxin, streptococcal, and antistreptolysin, relation between, 452
Antitoxin therapy of erysipelas, 43
Antrum, endonasal radical operation on the, 447
Aortic arch, congenital stenosis of the, 289
APERT, E.: Progressive ossifying myositis, 415
Apiol causing polyneuritis, 51
Appendicectomy in children, mortality of, 102
Appendicitis in measles, 328
Appendix operations, peritoneal drainage in, 25
ARONS, P.: Infections due to vitamin A deficiency, 140
Arsenobenzol, intraspinal, in treatment of tabes, 366
Arterial blood pressure during attacks of angina, 438
Arterial degeneration with calcinosis, 33
Arterial pressure in shock, 346
Arteries, experimental obliteration of the, 157
Artery, popliteal, embolectomy from, 426
Arthritis, acetylcholine in, 425
Arthritis, chronic: The blood volume in, 372—Endocrine aspects of, 257—Thyroid medication in, 397
Arthritis, rheumatoid, surgical treatment of, 204
Arthritis, roentgenotherapy in, 430
Artificial pneumothorax. *See* Pneumothorax
Aschheim-Zondek reaction, positive, in spurious pregnancy, 418
ASKEY, J. M.: Splenectomy in haemorrhagic purpura, 238
ASMUS, V. J.: Milkers' nodules, 341
Asthma, aetiology of, 217
Asthma, amytal and ephedrine in, 262
Asthma, bronchial, and atmospheric electricity, 58
ATKINS, R. G.: Treatment of minor injuries of the knee, 220
Atmospheric electricity. *See* Electricity
Atophan (cinchophen) jaundice, 357
ATTALEU: Writer's cramp, 141
Auricular [illegible] tic, 275
Auricular [illegible] cervix: pain in, 152
Avertin anaesthesia. [illegible] Anaesthesia

B.

Bacilli, enteric, rapid isolation of from the stools, 173
Bacillus Calmette-Guérin: Corneal inoculation of rabbits with, 118—Vaccine in the guinea-pig, 356
Bacillus coli infection and endocrine disturbance, 342
Bacillus proteus septicaemia, 72
Bacterial hypersensitivity and angioneurotic oedema, 119
Bacteriological researches in abdominal diseases, 252
Bacteriophage treatment of staphylococcal meningitis, 44
BAIZE, P.: Splenic extract in delayed dentition, 365
BAL[illegible] [illegible] sugar and insulin therapy in [illegible] t Bordeaux, 202
BALC[illegible] [illegible] mortality of abortions, 248
BALS[illegible]
BANG, O.: The stair-climbing test, 57
BARATOUX, J. E.: Primary malignant growths of the trachea, 311
BARBELLION, P.: The gono-reaction, 450
BARBOUR, O.: Endocrine therapy in whooping-cough, 242
BARKSDALE, I. S.: Simplified treatment of ringworm of the scalp, 227
BASKIN, M. J.: Temporary sterilization by injection of [illegible]
Basophilia. [illegible]
BASSI, Ugo: [illegible] of rabbits with B.C.G., 118
BAZY, L.: Choice of the anaesthetic, 211
BECKER, E.: Pathogenesis of diabetes, 358
BECLÈRE, C.: Accidental injection of blood vessels during salpingography, 371
BEERMAN, H.: Treatment of syphilis, 147
BENGAMIN, B.: Leucocytic reactions in measles, 139
BERCEY, J. E.: Quinine insufflation in trichomonas vaginitis, 297
BERGER, M.: Induction of labour, 352
BERGMAN, G.: Encephalitis following vaccination, 73
BERNARD, R.: Inflammatory complications of radium therapy, 283
BÉRODE, P.: Nervous complications of varicella, 237
BERTRAND, F.: Traumatic rupture of the liver, 409
Besredka's streptotoxin, intradermal reactions to, 121
Biceps, brachial, rupture of the tendon of, 162
BIGLER, J. A.: Tonsillectomy and the Schick test, 120
Biliary lithiasis: Treatment of, 41—Radiological diagnosis of, 432
BINET, Y.: Artificial pneumothorax and pregnancy, 285
BINGER, M. W.: Amytal and ephedrine in asthma, 262
Biopsy in cancer diagnosis, 338
BIRKHAUG, K. E.: Bacillus Calmette-Guérin vaccination in the guinea-pig, 356
BIRNBAUM, G. L.: Pneumococcal bronchial obstruction, 408
BISHOP, F. W.: Destruction of *Treponema pallidum* by pyrexia, 52
Bismarsen in established syphilis, failure of, 314
BITTER, S.: Glycosuria in pregnancy, 50
BJERRUM, O.: Incidence of actinomyces in the mouth, 175
Bladder: Ultra-violet radiation of the interior of the, 30
Blindness, changing causes of, 384
Blood in abdomen, detection of, 16
Blood alcohol, estimation of in drunkenness, 436
Blood changes in paralytic ileus, 69
Blood changes, post-operative, 405
[illegible] appearance of, 138
[illegible] x rays on, 431
[illegible] odies in, 387
Blood in pregnancy
Blood pressure, arterial, during attacks of angina, 438
Blood sedimentation rate in juvenile rheumatism, 17
Blood in serum sickness, 270
Blood sugar in diphtheria, 286
Blood supply, cerebral, and sphenoidal sinus infection, 246
Blood transfusion, prevention of chills following, 445
Blood transfusion, therapeutic value of, 224
Blood transfusion in typhoid fever, 165, 169
Blood and urine after marching, 203
Blood vessels, accidental injection of during salpingography, 371
Blood volume in chronic arthritis, 372

WITH SUPPLEMENT

No. 3757 SATURDAY, JANUARY 7, 1933 Price 1/3

ERYTHGEN
LIVER EXTRACT

A highly potent derivative of fresh liver containing the hematopoietic principles recently introduced in the treatment of anaemias.

Erythgen Liver Extract

permits the treatment of anaemias with the active principles in place of large quantities of liver.

Bottles of 8 oz. solution. Bottles of 100 capsules.

Dose: 1 to 4 teaspoonfuls three times daily.

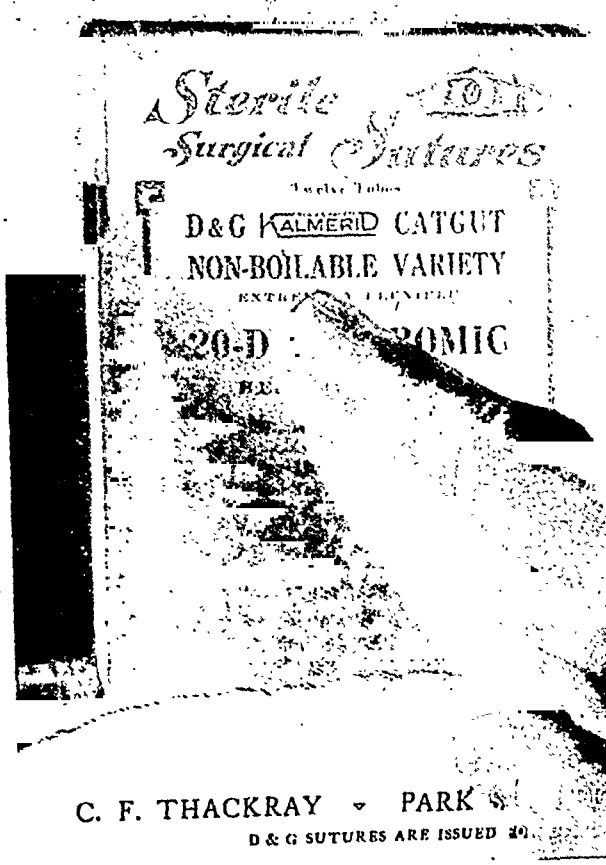
1 to 4 capsules three times daily.

G. W. CARNRICK CO.

Dependable Gland Products,

2-24, MT. PLEASANT AVENUE, NEWARK, NEW JERSEY.

London Agents: BROOKS & WARBURTON, LTD., 232/240, Vauxhall Bridge Road, S.W.1.



It is

EXTREMELY FLEXIBLE

Specify the NON-BOILABLE variety of D&G catgut. It embodies all the essentials of the perfect suture

C. F. THACKRAY ▪ PARK ST[illegible] ENT ST., LONDON, W. 1

D & G SUTURES ARE ISSUED [illegible] LICENCE 032-C

To Physicians treating

ASTHMA

a supply of—

Felsol

for clinical test sent on request.

'FELSOL' is a colourless crystalline powder of acid reaction, and somewhat bitter but not unpleasant taste. Easily administered by placing on the tongue and swallowing with a little water.

'FELSOL' contains no morphia or other narcotics.

'FELSOL' is equally efficacious in Angina pectoris and Dyspnoea in Phthisis.

BRITISH FELSOL COMPANY LTD.,
15, Caroline Street, London, W.C.1.

Telephone: Museum 2855.

Telegrams: Felsol, Westcent, London.

SAUNDERS' NEW BOOKS

COLON, RECTUM AND ANUS

A volume on any subject from the Mayo Clinic would be of immediate interest to the profession; but this new work, covering a region so frequently subject to disorders, will without question set up a new record of success. The work is both **medical and surgical.** First it tells you definitely how to arrive at an accurate diagnosis, with a full chapter devoted to history-taking and examination. There is an extremely enlightening discussion of chronic ulcerative colitis, with detailed instructions for the **concentrated serum treatment.** There are very definite discussions of carcinoma—its diagnosis and treatment; of **anal pruritus,** with a treatment that has brought relief in 92 per cent. of the cases treated; of haemorrhoids and their **injection treatment,** as well as the technique of haemorrhoidectomy. Over 100 pages are devoted to operative procedures which are, of course, fully illustrated. Indeed, no phase of the entire subject is neglected.

By FRED W. RANKIN, M.D., Division of Surgery; J. ARNOLD BARGEN, M.D., Division of Medicine; and LOUIS A. BUIE, M.D., Section on Proctology, The Mayo Clinic, Rochester, Minn. Octavo of 846 pages, with 435 Illustrations, some in colours. Cloth, 50*s.* net.

DISEASES OF THE THYROID GLAND

This volume is not a formal treatise on the thyroid gland, it is rather an account of the experience of the Staff of the Cleveland Clinic in the treatment of diseases of that organ. Chapters on the rôle of iodine in the organism and on the biochemistry of iodine are included, but the greater part of the book is devoted to an interpretation of clinical experience in the diagnosis and treatment of simple goitre, of hyperthyroidism, and of malignant tumours of the thyroid gland, and to discussions by various specialists of certain disorders of other organs which may be associated with hyperthyroidism.

By GEORGE CRILE and ASSOCIATES. Edited by AMY F. ROWLAND. Octavo of 508 pages, illustrated. Cloth, 32*s.* 6*d.* net.

ERDMANN'S CLINICS

This new book is a collection of the series of lectures given by Dr. John F. Erdmann before post-graduate students at the New York Post-graduate Medical School. The lectures cover virtually the entire range of surgery and are a record of the experience of a keen diagnostician and a skilful operator, who has the rare faculty of being able to impart to others his rich clinical knowledge.

By JOHN F. ERDMANN, M.D., F.A.C.S., Professor of Surgery in Columbia University, New York. Edited by J. WILLIAM HINTON, M.D., F.A.C.S., Associate Professor of Surgery, New York Post-graduate Medical School. Octavo of 315 pages. Cloth, 22*s.* 6*d.* net.

CLINICAL ENDOCRINOLOGY OF THE FEMALE

This is a **clinical book.** The presentation follows the sequential order of the functional phases of the woman—puberty, menstruation, pregnancy, lactation, and menopause. Realizing that the general practitioner first sees and frequently treats many cases coming under the heading of endocrinology, the authors have stressed diagnosis and treatment of the functional menstrual disorders, sterility, and menopause, devoting 150 pages to these conditions. This is decidedly a book for the general practitioner as well as for the gynaecologist.

By CHARLES MAZER, M.D., Assistant Professor of Gynecology and Obstetrics, Graduate School of the University of Pennsylvania; and LEOPOLD GOLDSTEIN, M.D., Demonstrator of Obstetrics, Jefferson Medical College. Octavo of 518 pages, illustrated. Cloth, 30*s.* net.

ELECTROSURGERY

The medical profession has impatiently awaited the publication of this book. **It is ready!**—the first complete and detailed presentation of the use of the **electric knife** in surgery. The book, beautifully and copiously illustrated, includes every condition where electrosurgery has been actually proved of value by the authors themselves. **It is a record of experience.** In addition there are discussions of electrodesiccation, electrocoagulation (surgical diathermy), acusection, preparation of the operating room, anaesthetics, instruments and their care.

By HOWARD A. KELLY, M.D., LL.D., F.A.C.S., Professor Emeritus of Gynecology, Johns Hopkins Medical School; and GRANT E. WARD, M.D., F.A.C.S., Assistant in Clinical Surgery, Johns Hopkins Medical School, and Instructor in Surgery at the University of Maryland. Large octavo of 305 pages, with 382 illustrations. Cloth, 35*s.* net.

MINOR SURGERY OF URINARY TRACT

Dr. Bumpus first describes the general preparation of patients, anaesthesia, the various solutions, equipment, etc. Then he takes up in detail the individual conditions of the urinary tract—caruncle, stricture, hypertrophy of the prostate, with **14 pages on transurethral ("punch") prostatectomy,** carcinoma of the prostate, contracture of the neck of the bladder, stones in the bladder and ureter, tumours, infection, and a special chapter on post-operative care. This final chapter includes a ful discussion of the **ketogenic diet,** giving menus, tables, and valuable comments. The diagnostic data are definite, as are the indications and contra-indications for treatment and the technique for treatment itself. Aiding in both diagnosis and treatment are many illustrations, clearly showing the procedures step by step.

By HERMON C. BUMPUS, Jr., M.D., F.A.C.S., Section on Urology, The Mayo Clinic. With a chapter on *Caruncles* by JOHN L. CRENSHAW, M.D., Section on Urology, The Mayo Clinic; and a chapter on *Postoperative Care* by ANSON L. CLARK, M.D., Section on Urology, The Mayo Clinic. Octavo of 124 pages, with 57 illustrations. Cloth, 15*s.* net.

Saunders' New Illustrated Catalogue sent post free on request.

NEW CAMBRIDGE BOOKS

CHEMICAL WAVE TRANSMISSION IN NERVE

By A. V. HILL

Demy 8vo. With 13 text-figures. 5s. net.

The author, a physiologist, in giving the Liversidge Lecture for "the encouragement of research in Chemistry," chose for his subject one in which the help of chemists, as well as engineers and physicists, is an essential condition of advance. It is his earnest hope that as a result of this book a chemist may come to the aid of physiologists in one of the most difficult and attractive scientific problems, the nature of the change which is transmitted in nerve.

"INTESTINAL CORRECTION" HERBARAS plant seeds are a specially selected perfectly sterilised species of the plantago family. The medical profession can prescribe them with confidence in cases of chronic constipation. "NEW HEALTH" (Organ of the "New Health Society") says: "The Herbaras plant seeds are very tiny, and when soaked in water swell up into a soft jelly—gently sweep along the walls of the intestines—collect the waste matter—leaving a clean and healthy bowel." Samples will be sent to any physician on request. Address Mr. JOHN W. LONGMAN, Foreign Produce Merchant and Importer, Clyde [illegible] 489a, Oxford Street, London, W.1.

THIS SUPPORT IS ECONOMICAL!

It combines style and support.

Spencer Supporting Corset, pictured above, is a light-weight, flexible garment, with inner abdominal support. Adjustment of the inner support is made from the OUTSIDE—a convenience women patients appreciate. As the support is in two sections, it is easily adjustable, providing uplift rather than compression. Special pads provided when prescribed.

ONE Spencer Garment takes the place of TWO other garments.

The woman of to-day is wearing corsets. Corsets are absolutely essential to the present mode. This means that if a woman is advised to wear a surgical support, the support *must* combine style essentials or she will be forced to buy a style garment in addition to her surgical one.

Spencer Corsets diplomatically combine surgical features and style essentials. Thus they are the most economical garments a doctor can prescribe. One Spencer takes the place of two other garments.

The Supporting Corset can be made to meet any number of surgical support requirements for one patient. Thus, one Spencer Garment can be designed to care for fallen stomach, hernia, movable kidney, a mild spinal curvature, all at the same time, without lessening the support value for any one condition.

Each Spencer Garment is designed individually for the one pre-determined woman who is to wear it.

The Spencer Corsetière in your town will call at your Surgery or at your patient's home to take measurements under your supervision. Spencer Supports and Corsets are never sold in shops.

Spencer Supporting Corset, shewn open, revealing adjustable abdominal support. Adjustment is made from outside the garment, for convenience.

FOR CONSTIPATION

Sal Hepatica, the proved, medicinal saline laxative and cholagogue is prompt, painless and thorough in its aperient action. It contains sodium phosphate which stimulates bile secretion and thereby avoids the habit-forming propensities of many other laxatives. Its regular administration re-establishes the daily habit of defecation.

Samples for clinical trial will be forwarded to duly qualified members of the medical profession on application to :—

BRISTOL-MYERS COMPANY LIMITED,

Thank goodness for Gas!

THE NEW WAY TO HOT WATER

'HOT,' says the nearside tap. Does it speak the truth? When you turn it on, are you immediately greeted by a reassuring gush of hot, *really* hot, water?

Yes—if you have installed one of the new gas water-heaters that serve every tap in the house, from bathroom to scullery, instantaneously, with water as hot as you want it. Automatically the gas goes down to a glimmer when the water reaches that temperature, and goes up again as hot water is drawn off. Very economical!

Visit your Gas Showrooms, see these new water-heaters for yourself, and marvel at their low running cost. Or the coupon below will bring you a free copy of a most informative booklet.

IN HÆMORRHOIDS

The Mental Effect

★ ★ EVEN though there is no acute pain, merely a sensation of discomfort, mental depression is a commonly observed symptom in hæmorrhoids. Constipation gives a feeling of weight as if the rectum were not properly emptied.

★ ★ Anusol Brand Hæmorrhoidal Suppositories, by their decongestive action and emollient effect, give early relief from pressure symptoms. In most instances painless evacuation occurs soon after introducing the suppository, because the contents of the rectum are softened.

★ ★ As the symptoms improve, mental depression disappears.

★ ★ Nothing gives such impressive reassurance to the patient as prompt treatment and early relief. This he will obtain if treatment is begun at the doctor's consulting room. Let us send you a trial supply for use immediately after examination.

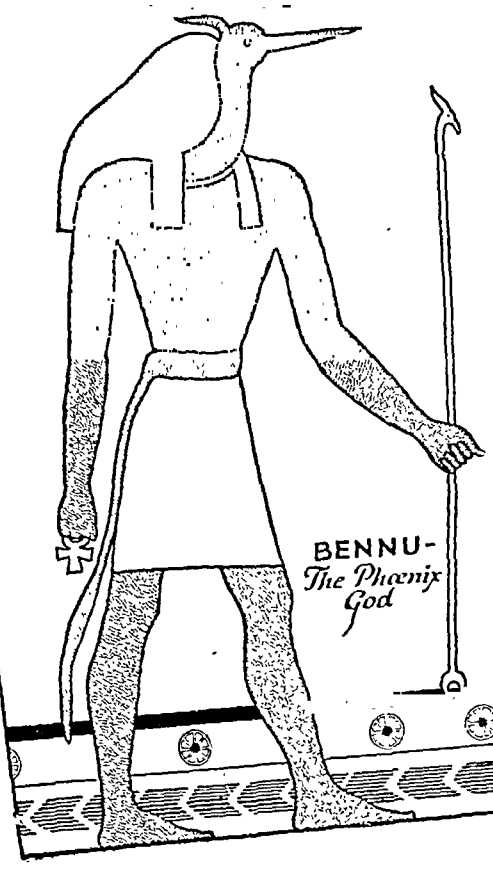
OVALTINE



BENNU—
The Phœnix God

IN NEURASTHENIA.

Every potential neurasthenic is greatly assisted by liberal drinking of "Ovaltine." It is recommended as a between-meals beverage or as a mid-day "light lunch," and it displaces tea or coffee with complete advantage.

"Ovaltine" is also invaluable when taken at the hour of sleep. Its use in this way has often avoided the need for employing hypnotic drugs.

The value of "Ovaltine" has been proved many times in such cases. It provides nourishment of the right kind, and in a form readily dealt with by the impaired digestive organs. "Ovaltine" permits of the liberal ingestion of food without taxing the digestive power.

"Ovaltine" is a complete natural food, yielding in one cupful a greater food value than three eggs. This delicious beverage is unquestionably a tonic nerve nutrient of a high order.

A liberal supply for clinical trial sent free on request.

RECENT TESTS

conducted by an eminent bio-chemist have demonstrated:—

1. That the proteins of Horlick's Malted Milk are quickly digested and absorbed, and readily utilized in the body.
2. That its carbohydrates are remarkably well tolerated. The ingestion of even large amounts of Horlick's caused no glycosuria.
3. That Horlick's brought about a better utilization of carbohydrates in general.
4. That anaemia induced in rats by putting them on a whole fresh milk diet was relieved by replacing the fresh milk with Horlick's Malted Milk.

An outstanding feature of these tests was the speed of the effect of Horlick's upon metabolism. The results confirm the clinical experiences of the past 50 years.

Horlick's Malted Milk is pure fresh cows' milk combined with the nutritive extracts of wheat and malted barley. Some 15% of the total caloric value is derived from protein. Horlick's, which has a marked protein-sparing and anti-ketogenic value, can be safely recommended in all cases associated with under-nutrition.

REINFORCED COD LIVER OIL
—BOOTS—

THE therapeutic value of Cod Liver Oil is fully appreciated by the medical profession. It is recognised for its specific action (due to its high content of Vitamins A and D) in Rickets, Affections of the Chest, and diseases arising out of Malnutrition. Reinforced Cod Liver Oil—Boots is a biologically controlled preparation containing five times the normal amount of Vitamin D in addition to the normal amount of Vitamin A. The advantage of a concentrated oil needing only a fifth of the usual dose will be appreciated. Four fluid ounces of Reinforced Cod Liver Oil—Boots, contain the same amount of Vitamin D as one pint of the finest Norwegian oil.

In 4-oz. bottles, 2/6

OBTAINABLE FROM NEARLY 1,000 BRANCHES IN GREAT BRITAIN

The symptoms of Partial Vitamin Deficiency and means of effective treatment have been disclosed by widespread therapeutic trials made recently with the co-operation of 1,124 independent practitioners.

Out of 2,000 Test Cases 90·1% showed definite improvement after taking BEMAX

The Medical Research Council's recent Report on Vitamins states that much subnormal health and development and low resistance to disease are associated with a partial deficiency of one or more vitamins.

A statistical investigation was recently carried out by our U.S. colleagues to determine with some precision the effects of this deficiency upon a test group of 2,000 persons, some healthy, some under medical treatment for illness. The cases were under the observation of 1,124 independent practitioners.

Results show that the regular administration of BEMAX was followed by definite improvement in health in 90.1% of these 2,000 cases, and its beneficial effect was observed in no less than 86.4% of those subjects who were supposedly normal. Some of the results recorded in definite conditions of illness are shown in the accompanying table.

The evidence seems to show conclusively that the normal diet is definitely deficient in Vitamins, especially Vitamin B, and that BEMAX is a source both adequate and effective for the restoration of normal metabolism.

A close analysis of the results of these 2,000 cases revealed that the typical clinical picture of Partial Vitamin Deficiency is general debility, loss of appetite, intestinal disturbance and constipation.

The medical reports in 2,000 test cases showed that the following percentages of people derived

BENEFIT FROM BEMAX	
CONSTIPATION	88.8%
ANOREXIA	80.0%
MALNUTRITION	78.4%
GENERAL DEBILITY and CONVALESCENCE	87.3%
INTESTINAL DISTURBANCES INCLUDING DYSPEPSIA and RECURRENT DIARRHOEA	81.0%

BEMAX

THE RICHEST NATURAL VITAMIN TONIC FOOD

Laboratory reports on Bemax and clinical sample will be sent to any physician on receipt of his professional card.

The most satisfactory form in which to administer Petroleum

Liquid Paraffin is repugnant to many fastidious patients because of its oily, greasy character. Occasionally it causes nausea and upsets the stomach. Frequently there is leakage which prohibits its continuous use. Even when taken readily and without these drawbacks, its failure to mingle with the food and with the fecal mass, lessens its full efficacy.

Angier's Emulsion is made with a specially purified petroleum of just the right degree of viscosity. It is palatable and freely taken by those who object to the plain oil; it does not nauseate or upset the stomach; it is readily miscible with water or milk; it mixes with the feces, keeping them soft and plastic and ensuring maximum lubrication; the characteristic action of petroleum is obtained with greater uniformity. Moreover *Angier's Emulsion aids Digestion and facilitates Assimilation.*

Thirty-nine years of clinical experience have demonstrated the foregoing so conclusively that countless physicians now look upon Angier's Emulsion as the most satisfactory and effective form in which to employ pure petroleum.

ANGIER'S EMULSION

Free Samples to the Medical Profession.

ANGIER CHEMICAL COMPANY, LIMITED, 86 CLERKENWELL ROAD, LONDON, E.C.1

Cadbury's BOURN-VITA

This food-drink contains 95% of bone-forming and energy-giving constituents. It is a palatable combination, containing malt, milk, eggs and cocoa. Easily digested and restorative, it induces refreshing sleep.

Alternative Methods in Prophylaxis and Treatment of

CORYZA

DETOXICATED ANTI-CORYZA VACCINE. This Vaccine has been used with great success for several years. Its outstanding feature is the absence of reaction, which makes it especially useful for hyper-sensitive patients.

ORDINARY ANTI-CORYZA VACCINE. Some Practitioners consider that a slight reaction has definite therapeutic value, and this type of Vaccine has been prepared to meet their requirements. It has the advantage of very low price.

ANTI-CORYZA VACCINE SPRAY (For local application to the nose and throat). For patients who object to Vaccine treatment by subcutaneous injection, and for children, this Local Immunity Product is particularly indicated. An additional convenience is that frequent attendances by the patient for injections are unnecessary.

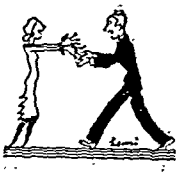
Additional information regarding the above products will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.

G A S T R I C *F A B L E S*

A TALE OF DOMESTIC HAPPINESS

She was a nagging nervous wife, he a raging irritable husband. They were told it was "all a question of diet." If the human animal is properly fed, he—or she—is likely to be amiable and easy going.

So he went on a three months' cure where fasting "alternated with carrots, salads, golden maize meal, porridge and plenty of milk." She too undertook a three months' rest and "a diet of cream, honey and raisins."



After three months they reunited; he more generous and less ferocious, she more docile and angelic. When regular food again threatened to disturb their domestic happiness, their physician recommended less drastic measures and prescribed CAL-BIS-NATE.

A wise physician, he knew that the suffering from gastric hyperacidity is likely to disturb the most amiable disposition. Instead of a freak diet, regulation of the stomach function is the rational remedy.

Cal-Bis-Nate is a combination of calcium and magnesium carbonates, sodium bicarbonate, bismuth and colloidal kaolin, blended into a palatable powder. It neutralizes excess gastric

acidity quickly, efficiently and with lasting effect. . . We will gladly explain the therapeutic merits of Cal-Bis-Nate and send a professional trial package for the asking. . . . Send for it.

In Gastric Hyperacidity— **CAL-BIS-NATE**

WHEN a mother is unable to nurse her infant, an alternative supply of suitable food becomes an urgent necessity.

■ ■ ■ ■

Cow's milk, in some form, is the only ordinarily available alternative. The predominating type of protein and the ratio of protein to fat and carbohydrate in cow's milk, though suited to the calf, differ markedly from those of human milk.

■ ■ ■ ■

'Humanisation' of cow's milk is therefore necessary. How this is successfully achieved in the case of the 'Allenburys' Modified Milk Foods will be described in future announcements.

This announcement regarding the 'Allenburys' Foods is No. 1 of a series which will be continued.

A TRAP FOR RECAPTURING THE SOUL OF A PERSON WHO HAS BEEN MADE ILL BY ITS ABSTRACTION BY SPIRITS.—The soul-trap illustrated is from Danger and Hervey Islands, and consists of a number of nooses suspended from a tree at night. It is closely watched by the medicine-man, who brings all his arts to bear upon the situation. Should an insect or small bird fly through one of the loops, it is asserted that this is the soul which has been carried off by the spirits, and, in the worst event, eaten by them. The loops, or nooses, are often graded in girth, as a fat person has a fat soul and a thin person a thin one. There is a great variety of snares and ambushes set for the stealing or recovering of souls. They are found in Africa, Hawaii, Indonesia, the Malay Peninsula, America and Canada.

THE TREATMENT OF CHILBLAINS

Colloidal Calcium
with Ostelin vitamin D

A sterile suspension for subcutaneous injection. Ensures intensive action of calcium and vitamin D. Held to be specific in the treatment of urticaria, chilblains, angio-neurotic oedema and other capillary vasomotor disorders. Invaluable in skin diseases such as psoriasis and eczema, in capillary haemorrhage, and in delayed union of fractures.

Boxes of six 1 c.c. ampoules, 5/-; 30 c.c. bottles, 10/-

VITAMINS A B D AND A & D

OSTOMALT

A very appetising preparation approximately three times as potent in vitamins A and D as Extract of Malt with Cod-Liver Oil B.P.C. Ostomalt is the family vitamin tonic. It is rich in anti-infective, calcium regulating, appetite creating, and nourishing components.

In jars 2/6, 4/-, and 21/-.

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1

Vitamin Therapy *a record of progress*

1924

OSTELIN LIQUID. The Glaxo Laboratories introduced "Ostelin"—the pioneer British concentrate of vitamin D. To-day all Ostelin preparations, liquid, tablets, emulsion, etc., are made from Calciferol G.L.—pure crystalline vitamin D.

1928

ADEXOLIN CAPSULES. The Glaxo Laboratories introduced Adexolin Capsules. Each three minim capsule contains vitamins A and D equivalent to that present in 10 grams of high-grade cod-liver oil. The vitamins are present in the proportions natural to cod-liver oil.

1932

ADEXOLIN LIQUID. The Glaxo Laboratories introduced a practically tasteless concentrate of vitamins A and D. Adexolin Liquid has twenty times the vitamin potency of high-grade cod-liver oil. This concentration was chosen to permit of the greatest flexibility of dosage. It is adapted ideally to administering the smallest prophylactic or largest therapeutic dose of these vitamins.

ON
AETIOLOGICAL FACTORS IN OSTEO-ARTHRITIS OF THE HIP-JOINT*
BY
R. C. ELMSLIE, M.S., F.R.C.S.
ORTHOPAEDIC SURGEON, ST. BARTHOLOMEW'S HOSPITAL
(*With Special Plate*)

steo-arthritis of the hip is a condition which presents characteristic clinical picture. When, however, the istory and the pathological changes as seen in *x*-ray hotographs are taken into account, it becomes clear that iere are a number of different aetiological factors. The iitial symptom may be pain or stiffness. The pain is iost often felt in the groin or down the inner side of the high. Sometimes, however, it extends down the sciatic erve, and occasionally at the onset it may be felt in the uttock or even in the back. There is progressive loss of iovement characterized particularly by diminution of bduction and of inward rotation, and this eventually eads to a fixed deformity, the joint becoming adducted, lexed, and rotated out. Finally, with complete fixation n this position, the pain tends to disappear. Most often nly one hip-joint is affected, although not rarely both ire involved.

Radiographic Changes and their Interpretation

The pathological changes as seen in radiographs, although they vary greatly in detail, conform fairly well in general type. Put quite briefly they are as follows:

1. Loss of joint space, which may show only in the upper part or may be seen all around the femoral head. This indicates a thinning or loss of the articular cartilage and consequent approximation of the bone surfaces.

2. Alteration in the contour of the femoral head, which may become flattened above and is often widened and spread out mushroom-like over the neck of the bone. The upper surface of the head in some cases becomes sclerosed, in others it is obviously worn away and rough.

3. The femoral head tends to become displaced upwards and outwards. This is sometimes due to the wearing and flattening above, sometimes to an actual subluxation. The inner part of the acetabulum, which thus no longer holds the normal femoral head, may be filled by the mushroom-like expansion of the latter over th[illegible] side of the neck, but sometimes it appears in radiographs to be empty.

4. The texture of the femoral head alters. There may be rarefaction of those portions of the bone which are no longer transmitting weight, with visible strengthening of that part between the calcar femorale and the summit of the head. In many radiographs it is obvious that the whole of the weight is transmitted through a limited portion of the top of the femoral head impinging against the corresponding part of the acetabulum. There is then very evident sclerosis of the bone in this region. In some cases there may be an irregular patchy rarefaction of the femoral head.

5. The acetabular margin is often extended outwards above in the form of a projecting osteophyte, and there may be further osteophytic outgrowths in other parts. At the upper margin of the acetabulum an accessory bone is frequently present (os acetabuli). This is sometimes mistaken for a detached osteophyte or even for a loose body. It is often seen in a normal hip-joint, and there seems to be no reason to connect it in any way with the development of osteo-arthritis. It is not unusual to find it shown quite clearly in a sound hip when there are osteo-arthritic changes on the other side.

6. The neck of the femur may be shortened and is often abnormally thick. When the head is much spread out and enlarged it may overlap the neck very extensively. This overlapping is most obvious on the anterior and mesial aspects, but often extends over the whole circumference.

When the details of these changes in the individual cases are considered we are often met with the difficulty of deciding to what extent they have resulted from the arthritis, or to what extent they may have been present before and have acted as mechanical causes of secondary arthritic changes. For example, when the femoral head is subluxated this may be the result of progressive disease or it may have been present as an old-standing and probably congenital deformity. The broad, flat, mushroomed head may undoubtedly be the result of an arthritis, but it may be a late stage of an old-standing coxa plana deformity which has been present from childhood, which has given rise to a hip-joint that is mechanically defective, and which has thus acted as a cause of the further changes that have occurred later in life. When the femoral head has worn away there may have been nutritional changes as the result of injury or disease, or presumably the bone may be soft simply because of senile atrophy. The rarefied patches seen may also be due to simple atrophy, or they may be in result from chemical changes, as, for e[illegible]

* Made in opening a discussion in the Section of the Centenary Meeting of the British Medical Associ 1932.

GENERAL DISCUSSION

The most satisfactory view to take of osteo-arthritis of the hip is that in it we see a series of degenerative changes in the joint which may result from any one or more of a number of causes. The anatomy and mechanics of the hip tend, however, to produce certain pathological reactions which bring cases due to many causes into a more or less uniform line of development, so that in the end, in spite of varying aetiological factors, we arrive at a clinical picture which becomes characteristic.

It may be as well here to consider the extent to which the various major joints are subject to osteo-arthritic changes. In the upper limb the shoulder and wrist are comparatively seldom affected. The elbow alone frequently undergoes changes in which the joint surfaces are eroded and osteophytes develop. In the lower limb the hip and knee are most often affected, the ankle seldom. It is possible that the comparative laxity of the shoulder- and wrist-joints tends to prevent bony changes occurring, so that, when arthritis affects these joints, rigidity and stiffness develop without the usual osteo-arthritic changes. In contrast with this the elbow and the hip show a very accurate fit between the bone surfaces. Walmsley has demonstrated that the femoral head is adjusted in the acetabulum so accurately that when fresh bones are entirely stripped of their ligaments the movements of the head of the femur are limited more or less to those which occur in the normal joint, and that particularly hyper-extension of the hip cannot occur even when all ligaments and muscles have been removed. Joints in which the bone surfaces are closely adapted in this way are particularly liable to strain and injury, and these are an undoubted factor in the production of osteo-arthritis. The occasional cases of this disease which occur in the ankle-joint almost invariably follow a Pott's fracture or other injury. Among the smaller joints, those of the thumb and big toe are not infrequently affected, and these are much exposed to injury.

TRAUMA AND DEFORMITY

Osteo-arthritis of the hip is far more common in men than in women, and occurs particularly in manual workers and in athletes. Strain and minor injury must be important factors, but in the majority of cases it is impossible to ascribe the condition to any particular accident. It is, however, not unusual to find that dislocation of the hip or an intracapsular fracture leads after an interval to the development of the characteristic degenerative changes. Presumably these accidents may cause nutritional changes in the head of the femur with loss of cartilage and wearing away of bone in the upper part of the joint. But sometimes an actual alteration of contour resulting from the injury, by varying the strain thrown upon the bone, may be the actual cause of the subsequent changes. Fractures of the marginal part of the acetabulum and complete fracture of the acetabulum burying the head deeper in the pelvis are also liable to produce osteo-arthritic changes.

Coxa vara, of either the adolescent or infantile type, results in a deformity which for years may cause comparatively little disability, but which often, later in life, gives rise to secondary changes that cause pain and increasing deformity and loss of movement. In the early stages of arthritis a radiograph may show quite clearly the nature of the pre-existing deformity, but later the secondary degenerative changes obscure this, and it sometimes becomes difficult to determine whether there has been any pre-existing deformity or whether the whole picture, as seen in the radiograph, is due to osteo-arthritis.

Coxa plana and congenital subluxation of the hip are also undoubted causes of late degenerative changes. Any other disease or defect arising earlier in life, such, for example, as changes due to an infective arthritis, may leave a mechanically imperfect joint, which will wear badly later in life. It is thus important to look carefully into the past history, and to try to determine whether there were any hip symptoms in childhood or adolescence. Unfortunately many cases of these hip deformities go unnoticed in childhood. It is, for instance, comparatively common at the present day to discover a subluxated hip either accidentally or because a radiograph is taken in young adult life on account of slight pain or disability. Many patients who develop osteo-arthritis at a comparatively early age—for example, at from 40 to 50—will be found to have a pre-existing deformity of the joint.

OTHER CAUSES

We now know that osteochondritis dissecans may affect the hip-joint. In radiographs the separating flake of bone may be seen on the upper surface of the head corresponding closely in appearance with what is seen in the knee-joint. We do not yet know much about this condition or about its subsequent history, but I think it is evident that any change of this nature must upset the mechanics of the joint. There are other cases also in which in adolescence or early adult life changes occur in the head of the femur resembling those seen in coxa plana—cases in which in the early stages there is still a clear joint space, sometimes actually wider than normal, suggesting the presence of a considerable layer of cartilage covering the upper surface of the femoral head. These cases also result in a mechanical misfit in the joint. We do not know whether they are traumatic or not, but they are certainly liable to lead on to further adaptive alterations, and probably eventually to degenerative changes.

When we come to consider factors other than trauma and deformity it is much more difficult to be sure of our facts. In a certain number of cases the toxic factor, such as dental sepsis, can be clearly proved and its connexion with the changes in the hip demonstrated, because removal of the toxic focus results in diminished pain and better function. In suspected dental sepsis an investigation should always be made on proper lines. It is not only useless to extract teeth wholesale, but this course tends to bring disrepute upon a line of treatment which is undoubtedly valuable in particular cases. The teeth should be investigated by *x*-ray photographs, and their clinical and radiographic condition discussed between the surgeon and the dentist, so that only needful extractions are carried out with other accessory dental treatment as necessary.

Apart from the toxic factor there are two definitely known chemical causes. Gout may be an undoubted factor, as was demonstrated in a case recently seen, in which the presence of patchy rarefaction of the head of the femur suggested this cause and was confirmed by the patient coming to the hospital with an acute attack of gout in his big toe. Family alcaptonuria gives rise to degenerative changes in the joints somewhat similar to those seen in gout. It is quite conceivable that further biochemical research will discover that there are other chemical poisons which may be concerned in the production of chronic arthritis.

BONE DISEASE

Another group of causes of osteo-arthritis includes local or general disease of the bone. In Paget's disease, when the articular ends of the bones become affected, there is a tendency to the production of osteo-arthritic changes which may be characterized by a rather rapid wearing away and destruction of the head of the femur. Occasional cases occur in which syphilis is an aetiological factor. In one of these there was a patchy rarefaction of the head of the femur, diminished joint space, and some extension of the margin of the head over the neck of the

The changes, in fact, could not be distinguished by *x*-ray appearances from any other case of osteo-arthritis.

Usually, changes of the osteo-arthritic type may take place in the hip-joint as the result of one of the forms of inflammatory articular arthritis. For example, the changes which occur in the hip in some cases of spondylitis deformans are very similar in character, and the late results of Still's disease upon this joint may closely resemble the destructive type of osteo-arthritis in *x*-ray photographs. The pathology of these diseases is at present entirely unknown.

There is no proof that bacterial infection can cause osteo-arthritis. In fact, the evidence is all against this. Where the changes initiated by an infection of the joint may be continued by secondary degenerative alterations in such a way that the eventual clinical and radiographic picture may closely resemble that of osteo-arthritis.

Conclusion

To sum up, the aetiological factors concerned in the production of osteo-arthritis of the hip may be classed as congenital, mechanical, toxic, chemical, and local disease of the articular ends of the bone. When once the degenerative changes have started, alterations occur in the shape of the bones entering into the articulation, so that whatever the original cause an additional mechanical factor is often induced. These alterations eventually give rise to the x-ray appearances which make it difficult to assess how much of the deformity is due to the arthritis and how much was pre-existent. There is, however, sufficient evidence of the importance of the mechanical factors in producing osteo-arthritis of the hip to make us think always of the possible late results when we are treating deformity of this joint earlier in life. So that we should always bear in mind that the mechanics of the joint should be kept as nearly natural as possible.

SURGICAL TREATMENT OF OSTEO-ARTHRITIS OF THE HIP*

BY

ERNEST W. HEY GROVES, F.R.C.S.

PROFESSOR OF SURGERY, BRISTOL UNIVERSITY

Osteo-arthritis of the hip presents itself in so many forms and varieties that it requires some preliminary classification and grouping of these different types before it is possible to discuss the treatment.

In the first place there are two well-marked types, which differ from one another in causation, course, and treatment. One is the "rheumatic gout" of old age, coming on very insidiously and affecting many joints and both sides of the body. It is often not very painful, but greatly disabling. Both pain and stiffness of the joints vary very much with the seasons, the weather, and

The other type occurs in much younger patients; only one joint is seriously affected, and there is a definite history of injury, which was clearly the cause of the trouble. This monarticular, traumatic form of the disease is not nearly so readily affected by changes in the physical conditions as the first.

But if the distinction between these two types is clear-cut, it must be admitted that there are many other types which are intermediate in character and origin. Two especially require mention before dealing with the problems of treatment. There is the case of toxic origin in which there is a well-established connexion between a septic focus and the origin of the disease. And there is the case which begins with a definite trauma, and then joints other than that injured are affected. For example, a neglected internal derangement of the knee will cause osteo-arthritis of that knee, and later, osteo-arthritis of the opposite knee and hips.

Dealing very briefly first of all with cases unsuitable for any operative treatment, it is true that these patients seldom come to the surgeon for advice, but if they do we should be able to give it to them. Such cases in the main are the multiple, spontaneous joint affections of age, when one or both hips are seriously implicated. There are two classes of remedy at our disposal—namely, apparatus and physiotherapy.

"Apparatus" is not very helpful. An elderly cripple will find any kind of calliper splint very irksome, and it would seem much better, therefore, to resort to the use of crutches, provided the hand grip is good. Before resorting to the surgeon the patient has usually tried whether physiotherapy can give him benefit; but, apart from this test of experience, there may be two valuable hints as to the likelihood of physico-mechanical methods relieving the pain and stiffness. These are the reaction of the patient to changes of weather and to exercise. If a patient says that his hip is better after exercise and that it is worse after resting, that it is better in hot weather and worse in the cold and damp, then physiotherapy is likely to be beneficial.

Forcible manipulation is, of course, the most potent form of mechanotherapy, and it is valuable in certain cases of monarticular arthritis for the relief of pain and muscle spasm. But it is certainly not indicated in the majority of cases, especially in senile conditions when both hips are affected. I would suggest that it is most likely to be of value in comparatively young patients, when only one hip is involved, and when *x* rays show that there is no great alteration in the articular bony surfaces.

Operative Treatment

Operative treatment is especially indicated in monarticular arthritis of comparatively young patients and in those cases where trauma has been a causative factor and pain a prominent result. Under these conditions I feel quite confident that operation can afford relief to all cases, but

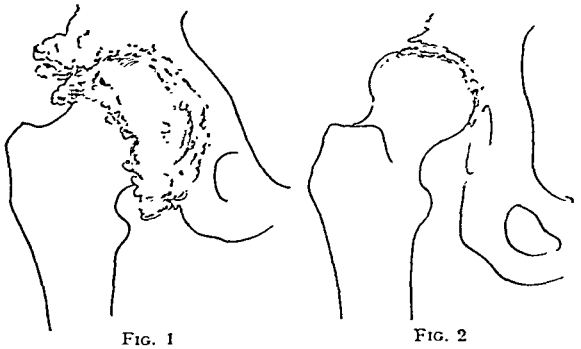

FIG. 1 FIG. 2

FIG. 1.—Common type of hypertrophic osteo-arthritis of hip with deep socket and exuberant osteophytes.

FIG. 2.—Another type, with subluxation and marked adduction.

it will require a nice judgement and a chastened experience to choose the right type of operation for each case.

Quite apart from small variations in the pathological changes, there are two widely different types of osteo-arthritic hips. In one, which is the rarer, the socket is shallow and inadequate, and there seems to be almost a subluxation, so little does the femoral head fit into the acetabulum (Fig. 2). Such cases are often old Perthes's disease or the result of congenital dislocation which has been reduced. In these cases there is often marked adduction of the leg, and the head of the femur looks as

* Read in opening a discussion in the Section of Orthopaedics at the Centenary Meeting of the British Medical Association, London, 1932.

if it was going to slip out of its socket. In the other, far commoner, type the socket is deep and the head large. There is so much osteophytic growth round the articular margin of the head that the neck of the femur is nearly as thick as the head (Fig. 1). Obviously the head has become too large for the socket, for though the latter is increased in its depth by additions to the rim, there is no general enlargement of the cavity, and it is clear that there is barely room for the femoral head in its socket and certainly no room for any synovial fluid to lubricate the joint. For this reason I think that the suggestion made by Rovsing of injecting vaseline into dry osteo-arthritic joints is impracticable. There is not room enough for the thickened head and neck, let alone any extraneous lubricant.

Cheilotomy and Arthroplasty

When one considers such a condition—namely, a greatly enlarged head with osteophytic outgrowths, spreading along the neck and a tightly embracing deep socket—it would seem obvious that both pain and stiffness must be due in large measure to the joint being as it were jammed by the tight fit of ball and socket. In the majority of such cases there is an exuberant candle-guttering of osteophytes round the margin of the femoral neck, and it has been suggested by that master of new phrases Sampson Handley that the chipping off of these osteophytes—which procedure he calls cheilotomy—will relieve the condition. But I believe this is an operation which by itself very seldom gives more than temporary relief. The osteophytes which are chipped off from the margin of the head only represent the fringe of the disease, the real centre of which is right inside the joint (Figs. 3 and 4).

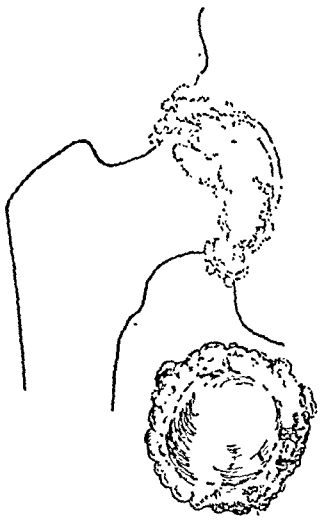

FIG. 3

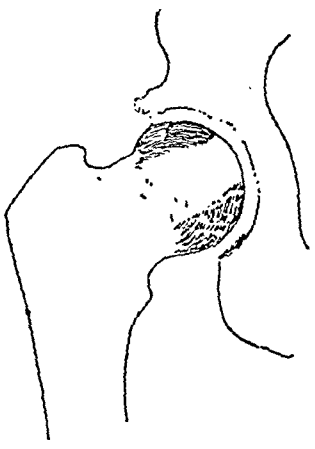

FIG. 4

FIG. 3.—"Cheilotomy"—the chipping off of the osteophytes.

FIG. 4.—The usual type of arthrodesis. Both joint surfaces being "refreshed." This inevitably leads to a widening of the joint space and hence is likely to fail.

It would seem imperative in these cases to relieve the tight-fitting joint, which strongly suggests a "seized" bearing in a machine. The ordinary way in which this is done is by a kind of arthroplasty, first dislocating the head and then reducing the size of it by chipping off not only the marginal osteophytes, but also a sufficient amount of the head of the femur to fit loosely into the acetabulum. There is, however, a difficulty in doing this effectively, because if the head be much reduced by removing its surface the cancellous tissue will be exposed, and this forms a very bad bearing surface.

There is another and better method of altering the disproportion between the ball and the socket of the joint, and that is to enlarge the socket by cutting away its lower and anterior margins. The joint must be dislocated from behind in order to get at the acetabulum, and then the projecting lip of bone together with the cotyloid cartilage is removed for rather more than the lower half of the circumference (Fig. 5).

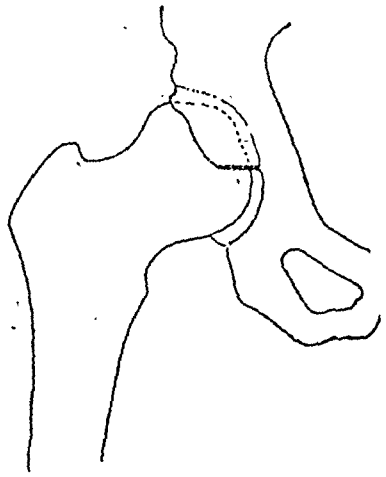

FIG. 5

FIG. 5.—A suggested form of arthroplasty, in which the rim of the acetabulum is removed below, in front, and behind so as to enlarge the joint space without making a raw surface on the head of the femur.

The more formal types of arthroplasty in which a flap of fascia is interposed between the joint surfaces hardly come into consideration, because they involve a very extensive operation upon tissues unsuitable for plastic work.

Arthrodesis

Undoubtedly the chief resource of operative surgery in the treatment of hip osteo-arthritis is some form of arthrodesis or fixation operation. The scope and indication for this procedure would be greatly increased if some really simple and efficient method could be devised. The indication for arthrodesis will be pain, made worse on movement and not relieved by physiotherapy, and affecting only one hip. Unfortunately both the general and local conditions are unfavourable for the healing of a bone-plastic operation.

The age of the patient, and tissues which are actually diseased or degenerated at the site of operation, do not make for rapid or certain union of bone surfaces; so that one is faced with an operation of some magnitude of which the result is doubtful. In these circumstances such an operation can hardly be urged, and if the risks and uncertainties are fairly put before the patient he will probably refuse. The theory of arthrodesis is good but its practice may be unsatisfactory, because of the danger and uncertainty which attends it.

Most methods of fixation of the hip have as their basis the baring of both articular surfaces—that is, the head of the femur and the acetabulum (*Fig. 4*). Now this is a long and difficult procedure, involving complete dislocation of the joint and a tedious chipping, gouging, and filing of the misshapen head and the deep socket. Further, it is open to the objection that the more of each articular surface is removed, the more loosely does the joint fit when put together again, and this very looseness of fitting is hostile to union.

The ideal arthrodesis would be achieved if we had some substance which could be injected into the joint cavity and which would produce a plastic inflammation, resulting in bony ankylosis. Possibly some chemical—for example, carbolic acid or a controlled bacterial preparation—may be found to carry out this idea.

In the meantime, we must rely upon a localized intra-articular arthrodesis or upon a purely extra-articular plastic operation. In the former case a horizontal osteotomy

made along the upper edge of the head and the ıet, and into this a flat bone graft is driven (Fig. 6). the latter procedure, a part of the great trochanter removed and fastened on to a raw surface of the ıer margin of the acetabulum and femoral neck. It the two great advantages of being practically an

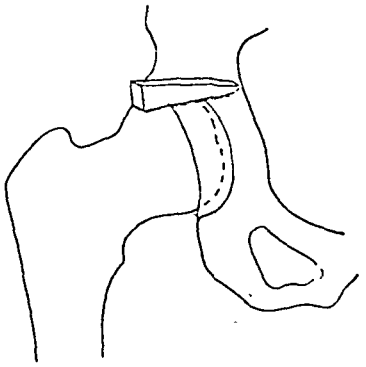

FIG. 6

IG. 6.—Arthrodesis, by driving a wedge-shaped bone graft into joint space above.

tra-articular procedure and of being much less shock-oducing than any of the classical types of intra-articular throdesis (Fig. 7).

Excision of Femoral Head: Osteotomy

There still remain for consideration two other operative ·ocedures, each of which has its definite place in treat-ent. These are, excision of the femoral head or a simple teotomy.

Excision of the head of the femur removes the chief te of pain and disease, and it leaves a mobile hip, but

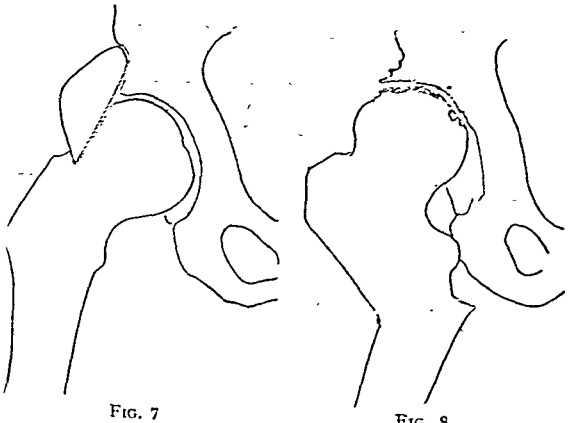

FIG. 7 FIG. 8

FIG. 7.—Extra-articular arthrodesis. The great trochanter is ısed as a graft applied to the upper surface of the socket and ıeck of the femur.

FIG. 8.—Osteotomy. This corrects the adduction, and the weight ıf the body is taken by the shaft of the femur rather than by he head.

these advantages are paid for by weakness and insta-bility, while it is impossible to promise a freedom from pain. It should therefore be reserved for severe cases of arthritis affecting both hips, the more painful side being operated upon. The patient should be warned that he will probably be dependent on crutches for walking.

Lastly, there is the operation of subtrochanteric or inter-trochanteric osteotomy (Fig. 8). The indication for this may not seem obvious at first sight, but I am convinced they are very real in special cases—that is, in cases where slow deformation of the head and neck of the femur have gone on to such a degree that a varoid deformity with the usual adduction of the thigh and raising of the pelvis has taken place. These are usually unilateral cases and there is apparently great shortening of the leg.

Much more is gained by this osteotomy than the mere correction of deformity and lengthening of the leg. The weight of the body is thrown more directly on to the line of the shaft of the femur instead of being transmitted altogether through the diseased head and neck. Also the thrust of the femur will be against the apex of the acetabulum and not all against its upper margin, whilst this thrust will also be shared by the shaft of the bone projecting against the lower margin of the sockets.

CONCLUSION AND SUMMARY

One fears that the recital of so many alternative methods of operative treatment will lead to the impression that none of them are very satisfactory. To some extent this is the case. Osteo-arthritis of the hip is essentially a process of wear and tear, resulting from two main factors—age and trauma—to which some toxic factor may be added in a minor degree.

Treatment must usually therefore be only palliative and not radical or curative. But on the other hand the relief of pain is a great achievement, and I say with considerable conviction that patients with hip osteo-arthritis treated by a well-chosen operation are nearly always very grateful and satisfied with the measure of relief afforded them.

The following summary of the indication for these various operative procedures may be made:

1. Marked osteophytic outgrowths, resulting from trauma and confined to one hip—*cheilotomy*.
2. Hip in which socket is deep, head and neck enlarged so that the joint has become "seized"—modified *arthroplasty*, either lessening the head or removing part of the socket.
3. Painful hip—*arthrodesis*.
4. *Double arthritis with stiffness of both hips and* much pain—*excision* on the worst side.
5. Cases with varoid deformity or subluxation—*osteotomy*.

SINUSITIS AND ITS RADIOLOGICAL DEMONSTRATION*

BY

H. K. GRAHAM HODGSON, C.V.O., M.R.C.P.

RADIOLOGIST, KING'S COLLEGE HOSPITAL, AND CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL

(With Special Plate)

Although the great utility and accuracy of radiology as a diagnostic aid in many pathological conditions has been universally recognized, its accuracy and possibilities when properly applied as a method of diagnosis in diseases of the accessory nasal sinuses have not been appreciated to anything approaching the proper extent. In laryngological textbooks scant heed is paid to the subject, and laryngologists—though not without reason—are disinclined to place much reliance on *x*-ray findings, and still less so if these findings conflict with their own clinical diagnoses. Yet hyperplastic changes, or fluid, in air-containing cavities in other parts of the body are constantly being demonstrated with extreme accuracy. The *x*-ray findings can be as accurate, if not more accurate, in the accessory nasal sinuses provided that the simple anatomical and physical facts of the problem are borne in mind. What are these facts?

GENERAL CONSIDERATIONS

When one *x*-rays the skull one is *x*-raying the most complicated bony structure in the body, throwing multiple shadows, widely differing in distance, size, and density,

* Paper read in the Section of Oto-Laryngology at the Centenary Meeting of the British Medical Association, London, 1932.

on to the single plane of the *x*-ray film. A small difference in the angle of incidence of the rays, in the point on the skull over which they are centred, or in the positioning of the patient's skull, will swing the shadows of structures a few inches away from the film through a wide arc and cause a big variation in their relative positions to structures closer to the film. Hence the absolute necessity for taking the radiograms at constant and standardized angles for every patient's skull, irrespective of individual differences in shape, for exact centring and angulation of the tube, and for taking several views from different standardized angles. In the majority of textbooks dealing with the subject one finds only three views mentioned—a lateral view, and two other views described respectively as the " nose-chin " and " nose-forehead " positions. These are not, in fact, " positions " at all, and the multiple shadows in the resulting radiograms depend for their situations relative to one another on nothing more accurate or scientific than the widely varying facial contours of individual patients. It is hopeless to expect accurate *x*-ray findings from such inaccurately taken *x*-ray films.

For example, Figs. 1 and 2 (see Plate) are two radiograms, both of the same patient. Fig. 1 was taken in the " nose-chin " position, and it will be seen that the lower parts of both antra are concealed by the shadows of the petrous bones, this being brought about by the patient having a long chin and a short nose. In this radiogram nothing abnormal can be detected. Yet Fig. 2, taken a few minutes later at the correct angle, throws the petrous bones clear of the antra and shows the right antrum to be half filled with pus.

This is only one illustration of the impossibility of demonstrating radiologically pathological conditions in the accessory nasal sinuses with any degree of accuracy by haphazard radiographic technique. Given correct radiographic technique the *x*-ray findings in the accessory nasal sinuses are as uniformly accurate as in any other part of the body—if not more so. My first point, therefore, is that one cannot over-emphasize the absolute necessity for accurate and standardized technique in the radiology of the accessory nasal sinuses.

Importance of Erect Posture

When *x*-ray apparatus gave only a small output, and before the days of duplitized films and intensifying screens, the exposures were very long, and the only position in which the patient could keep reasonably still was either the prone or the supine. In spite of the vast improvements in power and speed that have reduced the exposures to, at the most, a matter of six or eight seconds, by far the greater majority of *x*-ray examinations —with the exception of the chest—are carried out in the recumbent position. In the majority of instances there is no disadvantage in such a position, but it is definitely contraindicated when the part to be *x*-rayed is an air-containing cavity which may be abnormally opaque to *x* rays as a result of pathological changes in the mucosa or of pus. If one wishes to examine the contents of a glass jar, and to ascertain whether its content is solid or fluid, one does not look at it from above or below, as that would not give one the required information. One naturally holds it on a level with one's eyes, so that the light passes horizontally through the material to one's eye. In this position one can examine the structure of the material, see the upper border, and ascertain whether it is fluid or not by tilting the jar from side to side. If it is fluid, this upper border will remain horizontal whatever the position of the bottle. The same thing applies to the sinuses if they are *x*-rayed in the upright position. If they are *x*-rayed in the prone position gross pathological changes may easily escape detection.

Fig. 3, for instance, shows nothing much wrong beyond a slight degree of cloudiness in the antra. But the radiogram was taken in the prone position. Fig. 4 is a radiogram of the same patient, but taken in the erect posture a few minutes later, which shows a collection of pus in both antra. What happens is that in the prone position the fluid is spread out in a thin film over the antral wall, and when the amount is small it is insufficient to cast an appreciable shadow. In the erect position, however, the fluid is all collected into a pool in the lower part of the sinus, and is at once obvious.

Normal Transradiancy

Another possible source of error is the widely held assumption that the radiological detection of sinus infection depends on the observation that one sinus is more opaque than its fellow of the opposite side. One has only to consider the matter for a moment to appreciate how misleading radiological evidence based on this fallacy might often be. For, on the one hand, a sinus may be small and poorly developed with thick bony walls and consequent small air content, which, though non-pathological, is opaque when compared with the opposite normally developed sinus. On the other hand, a pair of sinuses may often contain an equal amount of pus or thickened lining membrane, and since both will allow an equal amount of rays to pass, they would both, on this assumption, be considered radiologically normal. The only safe and reasonable basis for radiological diagnosis is the radiologist's acquaintance with the normal degree of transradiancy which each sinus should give, according to its size and air content. This necessitates a thorough knowledge of the standard normal, and obviously can only be gained by taking the radiograms in standard positions.

STANDARD TECHNIQUE

It will be as well here to describe the six standard views which I use. They are all taken in the erect position, and at definite and accurately measured angles for every patient, irrespective of any difference in facial contour. For this purpose I designed the special " sinus stand " illustrated in Fig. 5. In each case I take six views as follows:

1. *Occipito-frontal View.*—The head is grasped by the head-clamp in the bi-temporal diameter and the head-clamp is adjusted so that the antero-posterior diameter of the skull

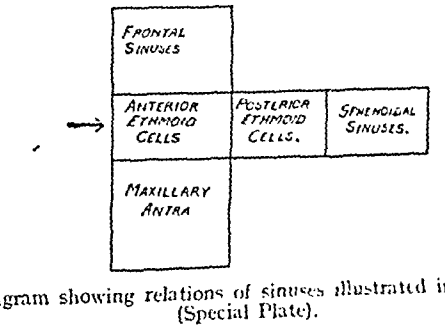

Diagram showing relations of sinuses illustrated in Fig. 6 (Special Plate).

is perpendicular to the film, the angle being read off on the dial. An imaginary line is taken joining the external auditory meatus and outer canthus of the eye, which for brevity I call the " orbito-meatal line." This line is so adjusted by means of a protractor that it is perpendicular to the film, the tube is centred half an inch below the external occipital protuberance and the exposure made. A typical result is shown in Fig. 6. The petrous bones will be seen to be thrown well above the antra in this position. The principal use of this view, however, is not to show the antra, but to show whether there is any abnormal opacity of the ethmoidal labyrinth or of the sphenoidal sinuses. On either side of the perpendicular plate of the ethmoid two air spaces are seen. These air spaces in this position consist of the superimposed shadows of the anterior and posterior ethmoidal cells and the sphenoidal sinuses from before backwards, and normally they are clear.

Occipital-mental View.—In this view, the head, still ɔed in the bi-temporal diameter, is so adjusted that the o-meatal line subtends an angle of 45 degrees to the film, angle being open towards the feet. The resulting radio- ı is shown in Fig. 7. In this position the petrous bones seen to be thrown clear below the antra, thereby giving ınmolested view of these sinuses. The anterior ethmoidal are thrown clear of the posterior group of sinuses, and frontal sinuses are well shown.

Vertico-mental View.—In this position the patient ex- ls the head as far back as possible on the neck. There obviously be no standard angle through which all patients extend the head, but this is compensated for by so tilting tube that, whatever this angle may be, the central ray :onstantly vertical to the patient's vertex. Fig. 8 gives ood view of the sphenoidal sinuses.

. *Right Oblique View.*—The head, still grasped in the np, is rotated through an angle of 39 degrees, the occiput ving towards the right. The chin is then depressed until orbito-meatal line is at 35 degrees, the tube being centred t behind the left mastoid process. This view throws the ıdows of the right posterior ethmoidal cells, and incidentally right optic foramen, into the shadow of the right orbit.

›. *Left Oblique View.*—This is the same as the right oblique w, but in this instance the occiput is rotated through degrees to the left, thereby showing the left posterior ımoidal cells (Fig. 9).

6. *Lateral View.*—This is an ordinary lateral view of the la turcica and accessory nasal sinuses, and is useful in ses of congenital absence of one or both frontal sinuses, and cases in which one or other antrum is poorly developed, th thick bony walls, and is consequently more or less opaque the anterior view. The lateral view throws into relief the ick bony walls, and consequently clears up the cause of the ›acity.

These, then, are the six standard views used in this :chnique. It will be seen that they are all necessary, nce they are ancillary to one another and each forms composite part of the whole. It will also be seen that, y using this technique, a radiogram taken in any given ne of these positions will correspond exactly, so far as he normal shadows are concerned, with the radiograms aken of any other patients in the same position. Thus, ›y this method any variation from the normal will be t once apparent to the experienced radiologist. Neces- arily, it takes a little time and experience to distinguish ıccurately each of the multiple normal shadows in each ›iew, even when they are invariably projected into the ›ame relative positions by the technique which I have described. One can imagine how unnecessarily difficult this becomes when they are thrown all over the film according to the prominence of the patient's nose, chin, or forehead, and how next to impossible it is—under such conditions—to recognize pathological changes with any approach to accuracy.

Results Obtained

It is entirely due to a haphazard technique that oto-laryngologists as a whole have hitherto placed little reliance on *x*-ray findings. It is my aim to show that radiology properly employed can give information regarding the condition of the sinuses which is not exceeded—and I doubt if it is equalled—by any other method of investigation as a preliminary to possible operation.

At King's College Hospital, and in my private practice, we have very carefully checked with our laryngological colleagues the proof puncture and operation findings in a consecutive series of 250 cases. In every one of these cases the *x*-ray findings were proved to be correct. When a fluid level was shown in the radiograms, immediate proof puncture was carried out. For a test like this such an immediate procedure was obviously necessary, as other- ›wise the pus might drain out in the interval. Such a trial of method necessarily entailed between our laryngo-logical colleagues and ourselves a very close co-operation, which is impracticable in ordinary routine work. But although, since that test group of cases, between three and four thousand examinations of the accessory nasal sinuses have been carried out, and we have frequently inquired as to the accuracy of the diagnoses, in not one instance have we heard or been informed of an error in the *x*-ray findings. On several occasions where the *x*-ray findings showed, on the one hand, thickened lining membrane but no fluid, or, on the other hand, a fluid content, proof puncture—*but* carried out several days later—showed the contrary. But in each of these cases the *x*-ray evidence of one or other condition was so definite that it was obvious, not only to ourselves but to the laryngologist himself, that the discrepancy was due to the filling or the emptying of the sinus in the interval between *x*-ray examination and the proof puncture. I think it is highly probable that where there is gross thickening of the lining membrane in the ethmoidal cells pus in one or more of the cells might be concealed by the general opacity of the superimposed cells. Also, in cases where there is marked hyperplasia of the mucosa, the outlines of, say, an antral polypus might easily be concealed by the general thickening of the mucosa. But taking the method as a whole, I have no doubt that you will find that radiology, properly applied, can be of the very greatest use to you. The method, as you see, is quite simple and straightforward, and, given the necessary apparatus and experience, any radiologist can carry it out.

Illustrative Cases

Further figures in the Special Plate illustrate the use and principles of this method in regard to sinusitis and other conditions.

It will be recalled that in Fig. 6, showing the occipito-frontal view, two air spaces are seen on either side of the perpendicular plate of the ethmoid. They consist (see diagram in text) of the superimposed shadows of the anterior and posterior ethmoidal cells and the sphenoidal sinuses from before backwards. Fig. 10 shows the space to the right to be opaque. Further radiograms having demonstrated that the anterior and posterior ethmoidal cells are clear, the vertico-mental view (Fig. 11) shows the opacity of the right space to be due to an infected sphenoidal sinus. It will be seen, therefore, that, starting with the occipito-frontal view, one has a double check on the condition of the ethmoidal labyrinth and the sphenoidal sinuses, which works out something like a game of patience. Occasionally, where there is unilateral deficient development of these sinuses, their comparatively thick bony walls will make the air space on that side opaque, although no pathological lesion is present. The other views, however, will show the reason for this opacity, while it must be borne in mind that if the angle is not exact the shadows of other structures will be thrown into the air spaces.

Fig. 12 illustrates another point. The horizontal line in the left antrum suggests that it is half full of fluid. That is an *assumption*, based on the horizontal upper margin. When the head is tilted to the left (Fig. 13) it is seen that the upper margin remains horizontal. Tilting to the opposite side (not shown) has a similar result. Nothing but fluid will remain horizontal in a cavity when that cavity is tilted. Thus the shadow is due to fluid, a fact based on *proof*, which can leave no shadow of doubt as to its accuracy. Fig. 14 shows fluid in a frontal sinus, confirmed by the tilt, while in Fig. 15 fluid can be seen in the sphenoidal sinuses.

A sinus may be transradiant or opaque to *x* rays. Opacity may be due to a fluid content or to dis-

ease of the wall, or to both, and *these are the only three possibilities.* The evaluation of normal transradiancy is a matter of experience, based on the size of the sinus, its air content, and the definition and clarity of the bony walls or foramina projected into the shadow of the sinus. With experience this can be accurately determined. The extent to which incontrovertible proof can be given by *x* rays regarding a fluid content has already been shown. With regard to the third possibility; since two are proved the third is simple. If a normally developed sinus is opaque to *x* rays and no fluid is present, the opacity must be due to thickening of the mucosa; I am, of course, excluding such comparatively rare conditions as new growth, bone disease, or thickening of the superimposed soft tissues, which, though demonstrable as such, do not enter into the scope of this paper. But quite apart from this proof by elimination, I believe I can show that not only thickening of the lining membrane, but the *type* of thickening, is as accurately demonstrable as fluid. However gross the hyperplasia may be it does not conceal fluid, except possibly in the case of the ethmoidal cells. Fig. 16 shows marked hyperplasia of the mucosa in both antra. It should be noted that, whereas at the periphery the rays are traversing the entire longitudinal thickness of the thickened mucosa, in the centre they are traversing the two layers of mucosa on the posterior and anterior walls, and consequently one sees a central comparative transradiancy if the penetration be increased to the correct degree. You will notice the thickened mucosa in both antra, and at the same time a horizontal level in the left antrum. The skull is tilted (Fig. 17), and the thickened membrane tilts with it; but the horizontal line in the centre of the left antrum remains horizontal, and therefore this sinus, in addition to thickened lining membrane, contains fluid.

Fig. 18 shows a different type of case. One sees an opacity occupying the lower half of the left antrum with a convex upper border, but there is a small gap between the upper part of its inner border and the antral wall. On tilting (Fig. 19) the upper margin tends to remain horizontal, but does not quite succeed in doing so, and the gap between its inner margin and the antral wall becomes wider. It is therefore fluid, but encysted fluid, and the obvious deduction is a cystic polypus. The diagnosis in this case was proved correct at operation.

A solitary polypus in the left antrum is seen in Fig. 20. Fig. 21 also shows polypi in the left antrum. In this picture is also seen the dense hard line around the periphery of the sinus. This is due to fibrosis of the periosteal layer of the mucosa, and is the result of long-standing infection. In acute and subacute conditions one sees, instead of the dense basal layer, a hazy, "ground-glass" appearance of the mucosa (see Fig. 22), which varies in opacity according to the duration of infection. It is caused by oedema and swelling of the mucosa proper. A slight degree of this oedematous swelling is usually seen following antral "wash-outs." Fig. 23 shows a similar acute or subacute "ground-glass" type of opacity in the right sphenoidal sinus, while in Fig. 24 is seen the chronic fibrotic type of hyperplasia, also in a sphenoidal sinus.

CONCLUSION

I have endeavoured to demonstrate in this paper, on the one hand, the impossibility of accurate *x*-ray diagnosis in the accessory nasal sinuses with the radiograms taken at haphazard angles or in the prone position, and, on the other hand, how accurate is the information obtained when the radiograms are taken at carefully measured and standardized angles and in the erect position. The underlying principles of the method are, I think, logical and obvious, and to any experienced radiologist the technique will be simple. I am sure that there is a very wide field of work to be carried out in co-operation between the laryngologist and the radiologist, and I have tried to indicate above a method of approaching that work. I hope that what I have said will be of use to both branches of the profession.

Before closing I should like to express my thanks to my laryngological colleagues at King's College Hospital and the Central London Throat, Nose and Ear Hospital, especially to Mr. Jenkins, Mr. Negus, Mr. Gill-Carey, and Mr. Cawthorne, for all their help and encouragement, and to my assistant, Mr. Crichlow, for his untiring zeal and energy. And last, but by no means least, I wish to thank Messrs. Newton and Wright of London, who took the greatest pains and trouble in manufacturing my sinus stand.

[In Fig. 17 for "tilted to left" read "tilted to right."]

ADENOMA OF ISLETS OF LANGERHANS ASSOCIATED WITH HYPOGLYCAEMIA

BY

R. McD. CAIRNS, M.D.

HONORARY PHYSICIAN, LEICESTER ROYAL INFIRMARY

AND

S. E. TANNER, M.D., M.R.C.P.

HONORARY ASSISTANT PHYSICIAN, LEICESTER ROYAL INFIRMARY

(With Special Plate)

Adenomata of the islets of Langerhans are rare, and up to the present time no case with clinical manifestations has been reported in this country.* We desire to record the following case, in which such an adenoma was present, associated with periodic attacks of hypoglycaemia, and ultimately proving fatal.

REVIEW OF REPORTED CASES

Warren[1] in 1926 was able to find in the literature records of only fifteen adenomata, though he himself added four more from his own experience, suggesting that these tumours may be more common than is supposed. He pointed out that little attention is paid to the pancreas in routine post-mortem examinations, and that small adenomata may be easily overlooked. He was of the opinion, however, that they were of no clinical significance.

The association of a pancreatic tumour with hypoglycaemia was not established until, in 1927, Wilder, Allen, Power, and Robertson,[2] in America, studied and reported a case in which the condition was caused by a carcinoma originating in the islet tissue. The patient was a physician aged 40. When specially observed, in a little over three hours after a meal he complained of a sense of apprehension and depression, with vague paraesthesiae; the blood sugar was found to be 0.055 per cent. Fifteen minutes later perspiration and trembling were noticed. Four hours later twitching of the face and incoherence of speech occurred, the blood sugar being 0.036 per cent. After four and a quarter hours he became stuporous, unable to speak, and developed convulsions. At this stage the blood sugar had fallen to 0.027 per cent. Fifteen grams of glucose were then given by the mouth, and in ten minutes he was capable of rational conversation, the blood sugar having risen to 0.065 per cent. The patient eventually succumbed, and at necropsy, in addition to the primary growth, metastases were found in the liver and lymph glands. It is of interest to note that the cells bore a striking resemblance to the cells of the islets of Langerhans, and that alcoholic extracts from cancer tissue in the liver had an insulin-like action when injected

* Since writing this paper we have seen that in the current issue of the *Journal of Pathology and Bacteriology* (November, 1932) W. G. Barnard reports a fatal case in a woman aged 40.

o rabbits. Previously, in 1924, Seale Harris[3] had rgested that a hyperfunction of the pancreas might pro-ce hyperinsulinism, and reported three cases with mild mptoms of hypoglycaemia. In 1928 Thalhimer and urphy[4] reported a fatal case of hypoglycaemia, and at cropsy a small tumour of the pancreas, measuring 1.5 · 1 cm., was found. Microscopically it appeared to have iginated from the islets of Langerhans, and some doubt as expressed as to whether it was a carcinoma or an lenoma. In the same year McClenahan and Norris[5] ported a case of hypoglycaemia with a history of eriodic attacks of loss of memory. At necropsy a large lenoma of the island cells was found, and, in addition, ie islands of the pancreas itself showed a general hyper-ophy. This latter condition, but with no tumour, was ound in a case of hypoglycaemia recorded by Phillips.[6]

The first successful removal of a pancreatic tumour in case of hypoglycaemia was reported by Howland, ampbell, Maltby, and Robinson[7] in 1929. There was six years' history of coma and convulsions, and at peration a slow-growing carcinoma was found in the niddle portion of the pancreas. In the same year Lloyd[8] ublished records of a woman, 22 years old, with a clinical istory of a cerebral tumour: a large adenoma of hypo-hyseal tissue, an adenoma-like enlargement of the para-hyroids, and an adenoma of the islands of Langerhans were found post mortem. Unfortunately, there was no sugar analysis of the blood. In 1931 several cases were reported. In Carr, Parker, Grove, and Fisher's[9] patient—a youth of 19 who had complained for a period of one year of recurrent convulsive attacks, diagnosed as epilepsy—a tumour was suspected and successfully removed at operation. It measured 2 cm. in diameter; microscopical examination showed it to be an adenoma, and suggested its origin from the beta cells of the islands. A similar successful removal of an adenoma was also recorded by Womack, Gnagi, and Graham.[10] The patient's attacks began with a feeling of hunger, which was soon followed by sweating, nervousness, tachycardia, muscular twitchings, disorientation, convulsions, and coma.

Smith and Siebel[11] gave details of four additional cases. In the first there was a definite clinical picture of hypoglycaemia, ending in death in coma. At necropsy an adenoma, 1 cm. in diameter, was found in the centre of the head of the pancreas. In the second an adenoma of the body of the pancreas was an incidental finding at post-mortem examination in a man dying from primary carcinoma of the liver. There was not the slightest clinical evidence of hypoglycaemia, and as far as they could see the tumour resembled very closely the tumour seen in the first case. Case three was also an incidental finding at necropsy, and there was a vague suggestion of hypoglycaemic symptoms. Mild diabetes had been observed in the last case—that of a woman who died from pneumonia, and in whom a well-encapsulated adenoma, measuring 1 cm. in diameter, was found in the centre of the body. Her past history gave no record of any hypoglycaemia.

History of Authors' Case

The patient was a married woman, aged 52, who had suffered from periodic attacks of giddiness since the spring of 1931 and during the last six months of her life from recurrent attacks of unconsciousness. She reached the menopause in November, 1930.

At the onset of her illness she began to have attacks of giddiness which came on practically every morning at 11 o'clock and lasted until her midday meal. During these attacks she had to stop her work, as she did not know what she was doing and was unable to speak, but she was conscious of what was happening around her. Her husband knew when these attacks were approaching, as she became fidgety and restless. In February, 1932, the character of her attacks changed, and for the first time she lost consciousness on this occasion for a period of four and a half hours. The following month she had similar attacks on two successive days. They recurred at intervals of two to four weeks, but were tending to become more frequent up to the time of admission to hospital on July 16th, 1932. There was nothing of note in the patient's personal or family history.

On examination the patient appeared a well-nourished woman, weighing 13 st., of good intelligence, and able to give a clear account of her illness. There was nothing abnormal to be noticed in her speech. Detailed examination of the central nervous system revealed no abnormality. The pulse was 80 per minute, regular, and of good volume; the blood pressure was 106 systolic and 64 diastolic. The heart and lungs were normal. Her appetite was good and bowels regular; there had been no loss of weight. The abdomen was well covered, and no abnormality could be detected on palpation. Urine was normal.

Special Investigations

Wassermann reaction in the blood was negative. Blood count showed: red cells, 4,000,000 per c.mm. (normal in shape and size); haemoglobin, 70 per cent.; colour index, 0.88; leucocytes, 8,124 per c.mm. Catheter specimen of urine was normal on microscopical examination. Blood bicarbonate 52.6 c.cm. bound by 100 c.cm. plasma; blood urea 28 mg. per 100 c.cm. blood. Basal metabolic rate—+ 15 per cent. Microscopical examination of faeces normal. X-ray examination of the skull showed nothing abnormal.

Progress of Case

During the four weeks following admission the patient had several attacks of a minor and two of a major character. In the former she became restless and confused mentally for a period of about two hours. In the latter, in addition to these symptoms, speech became slurring and incoherent, and she gradually passed into a stuporous condition, which persisted for about eight hours. On examination during these attacks the only abnormal physical sign noted in her nervous system was an extensor plantar response on both sides. The pupil reflexes were present, and the patient could be roused with some difficulty. During the fifth week these major attacks became of daily occurrence and were more severe in nature. At times she was completely comatose. During the intervals she was in a constant state of mental confusion and her speech resembled that of a drunken person.

At this time it occurred to one of us (S. E. T.) that the condition might be due to hypoglycaemia: this was confirmed by an analysis of the blood, which showed a sugar level of 0.041 per cent. Glucose was then administered four-hourly in 25-gram doses, by the mouth when possible and per rectum when the patient was unconscious. This, however, had no effect on the patient's condition, and on August 19th an intravenous injection of 20 grams of glucose was given. At the beginning of the injection the patient was comatose, but at the end—that is, in about half an hour's time—she roused to a certain extent, began to move her arms about, and became very restless. This improvement was only maintained for about one hour, and she then relapsed into her former coma. In spite of the continued rectal administration of glucose and injections of pituitrin and adrenaline the condition gradually became worse and she died the following day.

Analysis of the blood sugar on successive days showed the following results:

Date	Grams per Cent
August 15th	0.041
„ 17th	0.043
„ 18th	0.031
„ 19th	0.035 before 0.5 c.cm. pituitrin 0.037 half-hour after 0.5 c.cm. pituitrin 0.022 two hours after 0.5 c.cm. pituitrin
„ 20th	0.029

Following administration of 20 grams of glucose intravenously the results were:

Time	Blood Sugar, Grams per Cent.
0	0.051 comatose
½ hour	0.091
1 hour	0.071 conscious, but restless
1½ hours	0.053
2 hours	0.042 comatose

At no time was sugar found in the urine.

Post-Mortem Examination

Externally there was nothing of note. Internally the brain was normal. Apart from slight atheroma at the commencement of the aorta the heart was normal. The lungs showed a little congestion at the bases. The spleen, kidneys, stomach, intestines, and suprarenals were normal. The liver on section appeared pale. In the tail of the pancreas there was a small ovoid tumour, just under 2 cm. in length, which appeared encapsulated; the cut surface was of a grey colour, and, except for a few small haemorrhagic areas, homogeneous in appearance.

Microscopical Examination

The sections were stained with eosin and haematoxylin.

Pancreas.—The cells both of the acini and the islets appeared normal, and there was no excess of islet tissue.

Tumour.—The section showed a definite surrounding fibrous tissue capsule. The cells were arranged in groups separated by a fine connective-tissue stroma. Each group in composition and in the appearance of the individual cell resembled a normal island of Langerhans. The cells had round or slightly oval nuclei and the cytoplasm appeared slightly eosinophilic, in contradistinction to the more basophilic staining of the acinar cells seen in the section of the pancreas.

DISCUSSION

It is evident from the course of this woman's illness and the clinical investigation that she had been suffering from periodic attacks of hypoglycaemia for more than one year, and that for the last five weeks of her life these attacks had been increasing in frequency and severity. The similarity of her symptoms to those of hypoglycaemia induced by excessive doses of insulin is striking; the double extensor plantar response displayed by her has also been noticed in this condition. Banting, Campbell, and Fletcher,[12] in experiments with insulin, found that symptoms began to appear when the blood-sugar level had fallen to 0.07 per cent., while Sendrail and Planques[13] came to the conclusion that readings below 0.09 per cent. should be regarded as hypoglycaemia. In this case the highest percentage found was 0.043, and the lowest 0.022.

The fact that the sugar tolerance curve, following the intravenous glucose, runs parallel with the normal proves that the sugar was being removed from the blood in a normal manner. The consistently low sugar percentage, even after the continued administration of glucose, suggests very strongly that a constant excess of insulin was circulating. It is a reasonable assumption that the hyperinsulinism was the result of the secretory activity of the adenoma of the islets of Langerhans. This conclusion receives support from those American cases in which the removal of similar tumours resulted in the disappearance of symptoms. The failure to effect any permanent improvement with treatment is difficult to explain. In the early months of the illness the attacks appeared to have been relieved by the midday meal. A great increase in activity of the tumour must have taken place in the later stages. It is possible that insufficient glucose was given to counteract this. On the other hand, there may have been some other unknown factors responsible, seeing that our knowledge of the exact mode of action of insulin is still incomplete.

Since the only symptoms produced by an adenoma of the islands are those of hypoglycaemia, it is important from the point of view of treatment to consider what other causes can give rise to this condition, and on what grounds it is possible to suspect the presence of such a tumour. Hypoglycaemia, apart, of course, from that induced by insulin overdosage, may be produced by various dysfunctions, which may be briefly grouped as: (1) hepatic, (2) endocrinal, and (3) pancreatic.

In the first group hypoglycaemia may result from a defect in sugar mobilization or sugar storage, and has been found in cases in which parenchymatous changes in the liver cells have followed poisoning with chloroform, arsphenamine, phosphorus, and hydrazine.[6] It has also been observed in primary carcinoma of the liver.[14] In the second it is well known that a low blood-sugar level can be brought about by the loss of substances antagonistic to insulin—as in hypo-adrenalinism, hypothyroidism, and diminished activity of the posterior lobe of the pituitary gland. In the third the syndrome is brought about by over-production of insulin. Several cases have been reported under the title of "spontaneous hypoglycaemia," in which no anatomical change has been found in the pancreas, and the condition was assumed to be due to a hyperfunction of the islet tissue.[15 16] The evidence for this is somewhat inconclusive. Certain American cases[17 18] have undergone operation and massive resections of the pancreas have been carried out, with only partial improvement in the symptoms. It is possible that some of these cases may be due to conditions outside the pancreas. In others of this group a general hypertrophy of islet tissue has been found. Lastly, a definite tumour, an adenoma or carcinoma of the islets, as in the cases already discussed, is the responsible agent.

From a review of the literature of these pancreatic cases it does not seem possible to separate clinically the various types with any degree of certainty. On the whole, it would appear that, whereas in the group with no demonstrable change in the pancreas the hypoglycaemia can be controlled by dietetic measures, in the others this is true up to a point; but beyond this the response becomes incomplete and progressively unsatisfactory, ending, if no surgical measures are undertaken, in the death of the patient.

Pathology

Some doubt has been expressed by certain writers, notably Bensley, who examined Womack's case,[19] as to whether these tumours should be regarded as adenomata or slowly growing carcinomata. Smith and Siebel are inclined to consider all their cases as adenomata. In our case the presence of a definite surrounding capsule is strong evidence for its being an adenoma. The arrangement and appearance of the cells would point to its origin from the cells of the islands of Langerhans, although the tissue was not properly fixed for demonstrating the alpha and beta granules. Bensley thinks that the cells differ from the normal in their granular structure, and regards them as atypical beta cells, which in cases with hypoglycaemia are not responsive to the ordinary pancreatic mechanism controlling the liberation of insulin. The pancreas possesses a large reserve of island tissue and is capable of producing many times more insulin than is required by the body, and it is difficult to understand how a small adenoma can produce hypoglycaemia without such an hypothesis.

In the recorded cases the islands of the pancreas itself have been found normal, with the exception of that of McClenahan and Norris,[5] in which they were stated to be hypertrophied. A diminished sugar tolerance has been noted in some, but from anatomical studies no evidence

ıy depressed activity of the normal cells has been ınstrated.[11] In our case the pancreatic islands were to be normal, and in the one test performed there was vidence of any decreased tolerance.

Conclusion

A case of adenoma of the islands of Langerhans asso- d with hypoglycaemia is reported.

It is suggested that in a case of hypoglycaemia, not rolled by dietetic measures, a tumour of the islands angerhans should be suspected.

'e desire to express our thanks to Dr. W. D. Jeans for the aration of the photomicrographs, and to Miss M. Staynes, :., for carrying out the numerous biochemical analyses.

PANCREATIC CYSTS

BY

DAVID SMITH, M.D., F.R.F.P.S.

ASSISTANT PHYSICIAN, ROYAL INFIRMARY, GLASGOW

(*With Special Plate*)

ancreatic cysts are uncommon, and although they are .ven a place in differential diagnosis of upper abdominal iseases it is difficult to assert with any degree of finality ıat a pancreatic cyst is present unless the clinical exam- ıation has been corroborated by radiography. In fact, here no physical signs are present routine radiography the only means by which the abnormality can be lemonstrated. The purpose of this paper is to relate ıow an intercurrent acute illness revealed the presence ıf a pancreatic cyst which was not giving rise to definite liagnostic symptoms or physical signs.

The rarity of pancreatic cysts is shown by some of the published figures. Hale-White[1] collected four cases in nearly 6,000 necropsies performed at Guy's Hospital from 1883 to 1894. Körte[2] collected 177 cases from the literature up to 1902, and Mayo Robson and Cammidge[3] 175 up to 1907. Guleke[4] reviewed 260 cases in the surgical literature up to 1912. Wangensteen[5] reports three cases from the Department of Surgery, University of Minnesota, during the years 1926–30. Friedenwald and Cullen[6] describe seven cases operated on between 1904 and 1925. Carslaw[7] details an interesting case in the *Lancet* in 1921. It is very evident from perusal of the literature that the condition has occupied the minds of surgeons and pathologists more than physicians. Cases of successful extirpation were recorded by Bozeman[8] as early as 1882, and many other successes are on record after that date. It is interesting to note that Bozeman operated for the purpose of dealing with an ovarian cyst, but found instead one in the pancreas. In 1883 Gussenbauer[9] described operations on pancreatic cysts, and showed how gastric and colonic inflation were useful methods of investigation.

The case which is here to be described has several points of interest: (1) the diagnosis was made in the course of routine radiography; (2) the aetiological factors concerned in the production of a pancreatic cyst were proved to be present; (3) an acute intercurrent illness precipitated a fatal issue; (4) although complete destruction of the pancreas had taken place there was no glycosuria and no increase in the blood sugar.

Case Record

The patient, a female aged 45, had enjoyed good health until about five years before seeking medical advice on July 27th, 1928. Her symptoms began with pain in the region of the stomach, felt most acutely in the mid-line. She did not pay much attention to her condition, and later began to have pain in the right hypochondrium, which was most intense in the region of the gall-bladder. She had discomfort from flatulence, and sometimes had an aching in the back and a sharp pain in the right shoulder. Some relief was obtained from vomiting, and at times she was jaundiced after an attack. She considered herself "bilious" and was told she had gall-stones, but no special examinations were carried out.

Apart from these attacks she made no complaint until July 20th, 1928, when she was seized with severe pain in the whole upper abdomen, which was more marked under the right costal margin. She vomited, and in the vomitus noticed portions of pie she had eaten the previous evening. Soon afterwards she had acute diarrhoea with colic. She was on holiday at the time, and the doctor who was called in diagnosed acute gastro-enteritis. She improved under treatment and returned home on July 26th. There is no record of pulse, temperature, or respirations during this attack, but she stated that she was "fevered."

The following day (July 27th), she did not feel well, and as there was a recurrence of vomiting and diarrhoea she was admitted to hospital with a temperature of 100° F., pulse 120, respirations 20. On admission her symptoms had disappeared, and physical examination was absolutely negative except for slight resistance to palpation over the whole abdomen. No swelling was visible, and no abnormality was detected on palpation or percussion. The liver and spleen were not enlarged. The bowels moved well, and she partook of light diet without discomfort. Her general condition rapidly improved, and she was allowed up on August 3rd. When she was up she complained of pain which was most marked in the right hypochondrium and spread downwards towards the umbilicus. She was considered to be suffering from cholecystitis and cholelithiasis, and preparatory to having the gall-bladder *x*-rayed she was given a barium meal on August 7th. This showed a marked spreading out of the duodenum and a displacement of the transverse colon downwards (see Plate). From the appearances a diagnosis of pancreatic cyst was made.

Operation

In the light of the radiological finding a further physical examination was carried out, but no abnormality could be detected except increased resistance in the upper abdomen. The blood sugar was 0.08 per cent., and there was no sugar in the urine. The Wassermann and van den Bergh reactions were negative. The blood picture was normal, the eosinophils being 2 per cent. in a differential count. Operation was decided on, but after her acute gastro-enteritis a few days' convalescence was thought advisable, especially as she was free from symptoms.

On August 16th she suddenly became ill. Her temperature rose to 101.5° F., and her pulse to 124. She complained of agonizing pain in the right hypochondrium and epigastrium and became slightly jaundiced. Physical examination revealed tenderness and marked resistance to palpation, and an indefinite mass in the epigastrium and right hypochondrium. The leucocyte count rose to 21,812 per c.mm. There was excess of polymorphs but no increase in eosinophils. The van den Bergh test showed a direct biphasic reaction. Immediate operation was undertaken. A right paramedian incision was made and the cyst exposed. On an attempt

to deal with it the wall ruptured, and there was a rush of dark blood-stained fluid. Extensive fat necrosis was noted. There were dense adhesions round the stomach and adjacent viscera. The patient became collapsed, the cavity was packed, and no further procedure was deemed advisable. After operation the blood sugar was 0.16 per cent., the previous readings having varied between 0.06 and 0.08 per cent.; no sugar was present in the urine. The patient died nine hours after operation.

Post-mortem Findings

The necropsy was conducted by the late Professor Teacher. The body was that of a fairly well nourished but very anaemic woman. There was a yellowish tint but no definite jaundice. There was an abdominal wound in the region of the gall-bladder. Heart and lungs were normal except for some old pleural adhesions over both lungs.

There was a certain amount of blood clot about the field of operation, but, on separation of this, widespread old adhesions were found. There was a large mass of fairly firm consistence behind the stomach and duodenum. Extensive fat necrosis was present; this was old, the patches breaking down under the finger. The liver showed extensive fatty change. The gall-bladder was full of fluid bile and contained a cholesterol gall-stone about the size of a marble. The ducts were patent, although pressed upon by the stone. The stomach was soft, rather dilated, and contained quantities of stringy mucus: no ulceration, but marked chronic catarrh. The duodenum showed no ulceration, but was stretched round the right end of a tense cyst.

The bile papilla was prominent and patent, but the pancreatic ducts were obliterated and no trace of pancreatic tissue was found. On cutting into the cyst a large amount of thin bloody fluid escaped; this was evidently serum from great masses of blood clot which occupied most of the cavity. A large mass of slough was found in the cavity: it was dark grey in colour and completely necrotic. Its nature was not certain, but it seemed most probable that it was the remains of the pancreas, dead and dissected out. The cyst on this theory was a retention cyst due to chronic pancreatitis, with haemorrhages which had lasted an unusually long time. Nothing of importance was found in any of the other organs.

Classification of Pancreatic Cysts

Mayo Robson and Cammidge[3] classify pancreatic cysts as:

1. *Retention cysts*, which are lined with epithelium and are caused by obstruction in the pancreatic duct, smaller ducts, or acini.

2. *Proliferation cysts*, due to proliferation of glandular epithelium followed by accumulation of fluid.

3. *Congenital cysts*, which are frequently multiple and associated with cystic disease in other organs.

4. *Haemorrhagic cysts*, due to haemorrhagic necrosis.

5. *Hydatid cysts*, which may be associated with hydatid changes in the liver or elsewhere.

6. *Pseudocysts*, produced by trauma or degenerative changes of the interstitial tissue of the pancreas. They are not within the substance of the pancreas, but outside it and usually in the lesser omental sac.

A seventh type has been added by Primrose[10]—namely, *dermoid cysts*. This type is also referred to by Judd[11] and Dennis.[12]

Aetiology

Many causes have been ascribed to the formation of pancreatic cysts. Of these the most important are acute and chronic pancreatitis, especially of the interstitial type. By fibrous contraction pressure is borne on the ducts, and infection then produces the true retention cyst. Cholecystitis and cholelithiasis also act by occluding the ducts, and the end-result is the same. In the case recorded above there is clinical evidence of cholecystitis and cholelithiasis preceding the final diagnosis of pancreatic cyst, and this was proved post mortem. In addition, the pancreatic ducts were shown to be obliterated. It is therefore a reasonable assumption that pressure on the bile and pancreatic ducts was present and caused obliteration of the latter. The clinical history of jaundice at intervals suggests that the bile duct was from time to time obstructed. The acute gastro-enteritis from which the patient suffered provided the final infection, and, no doubt, determined the acute terminal illness. From the history the case can be regarded as a retention cyst with a final excessive haemorrhage. Judd[11] of the Mayo Clinic thoroughly describes the aetiological significance of gall-bladder disease in pancreatic cyst formation.

Proliferation cysts are uncommon and, as Oser[13] points out, are due as a rule to cystic changes in tumours or to degeneration similar to that occurring in the kidney. Congenital cystic changes in the pancreas are rarely met with, and are, as a rule, part of cystic anomalies in other organs. Mayo Robson and Moynihan[20] refer to three cases. Haemorrhagic cysts usually develop in the tail of the pancreas, and the haemorrhage is the primary condition. Trauma is often noted as a cause, but it is often impossible to differentiate this type from one similar to the case under discussion, in which haemorrhage into the cyst appeared to be terminal. The aetiological factors which would exclude this case from being classified as haemorrhagic are: (1) no history of trauma; and (2) *x*-ray examination showed the cyst to be more in the head than in the tail of the pancreas. Hydatid cysts are accompanied by a definite eosinophilia, and are due to echinococcal infection. Pseudocysts generally occupy the lesser omental sac and are peripancreatic. Trauma almost always plays a definite part in aetiology. Dermoid cysts are rare, and at operation or post mortem definite evidence of their character is found. Trauma is undoubtedly of importance in certain cases and in certain types of cyst formation. Honigman[14] collected seventy cases in which abdominal trauma preceded pancreatic cyst formation.

From experimental work the exact aetiology is inconclusive. Ligation of the pancreatic duct has been performed by Senn,[15] and he produced slight dilatation of the duct beyond the ligature. Thiroloix[16] produced a cyst by ligation and injection of a mixture of soot and carbonized liquid vaseline. Lazarus[17] experimented by first injuring the pancreas by crushing, and he succeeded in producing a haematoma which developed cystic formation on a small scale in forty days. These experiments, however, are no more conclusive than clinical observations, such as those made by Horrocks and Morton.[18] They record large cysts occurring where cholecystitis is associated with the pressure of a large stone lodged near the orifice of the pancreatic duct.

Cysts of the pancreas may suddenly enlarge, due to haemorrhage within the cyst, and that appears to be what has occurred in the case under review.

There is no definite age incidence, although they are mostly observed in middle life. The sexes are more or less equally affected. Some authorities consider the condition occurs more frequently in men, and give this as a reason for denying the importance of cholecystitis as an aetiological factor and upholding the traumatic theory.

Malignant degeneration is not uncommon, and likewise cystic degeneration of malignant and simple pancreatic tumours sometimes takes place.

Symptoms and Signs

The symptoms are based on personal observation of three cases and a perusal of the literature. At first symptoms may be absent. A careful history usually elicits a train of complaints more or less characteristic of cholecystitis or mild cholelithiasis. If enlargement takes place pain from pressure and tension becomes more marked.

mptoms referable to pressure on other organs may e manifest. At times the symptoms are associated o-called "bilious attacks," and extreme cases may te intestinal obstruction. Pain or a feeling of dis- rt and distension are felt in the epigastrium, but cyst is confined to the head or the tail of the as then symptoms are usually referred to the right the left hypochondrium respectively. Anorexia is on. Glycosuria is usually noted in cases in which hole pancreas is involved, but in my patient there o sugar in the urine and the blood sugar was normal, u there was no sign of pancreatic tissue found at t-mortem examination.

clinical signs are progressive enlargement of the men with palpable tumour between the xiphisternum he umbilicus. The enlargement may be to one or side and moves with respiration. There may be a thrill, but sometimes this is absent on account of high tension of the encysted fluid. A radiological mination will always make the diagnosis clear.

Diagnosis: Direct and Differential

e diagnosis usually is made definite by a period of ptoms terminating in a gradually increasing abdomen h conforms to the type described. Sometimes the our presses on the common bile duct, producing idice. When the involvement of the pancreas is con- rable large fatty stools may be passed and sugar is erved in the urine. Duodenal intubation gives very e information, though Einhorn[19] reports a diminution ipsin and trypsin in his cases.

ydatid cysts of the liver cause difficulty in differential osis only when the cyst in the pancreas is of a latid type, for otherwise distinct eosinophilia will help the differentiation. Cysts of the liver also displace the ow viscera either downwards or backwards. Omental mesenteric cysts may also lead to confusion, but the position in the abdomen and the accompanying al irritation with ascites will help to differentiate. drops of the gall-bladder may give rise to doubt, but greater respiratory excursion and the continuity with liver serve to elucidate the diagnosis. Pelvic tumours ly give much difficulty if a vaginal examination is ried out and one remembers that in ovarian cysts the llow viscera tend to be pushed backwards and in pan- atic cysts forwards. In hydronephrosis the tumour is lt more in the lumbar region. The history helps con- derably, and a complete urological examination will etermine the issue.

Complications and Treatment

The main complications are: (1) haemorrhage into the st; (2) perforation into the peritoneal cavity or intestinal tract with fat necrosis; (3) extreme emaciation and lycosuria; and (4) malignant degeneration. It is inter- sting to note that no diabetes occurred in my case, hough Wangensteen[5] states that

"diabetes is an occasional complication of pancreatic cyst, specially in those instances in which excessive degenerative changes are present in the pancreas. In true cysts of the pancreas following upon attacks of acute pancreatitis in which gangrene or slowing of a good portion of the tail of the pancreas occurs diabetes is unavoidable."

The treatment is wholly surgical. Extirpation of the cyst is not uncommonly followed by a true diabetes. This happened in one patient in whom I observed a post-operative diabetes. A typical diabetes as regards symptoms was produced with marked glycosuria (31.2 grains per ounce), but there was a comparatively low blood sugar (0.14 per cent.). This is difficult to understand. This patient had no glycosuria, hyperglycaemia, or diabetic symptoms before operation; yet she developed post-operative diabetes, though extirpation of the cyst was carried out very successfully.

Summary

1. A case of pancreatic cyst of the retention type has been described.

2. The case was complicated by haemorrhage into the cyst.

3. Radiography was of the utmost value.

4. There is danger of an acute infection of the alimentary tract precipitating a rapidly fatal issue.

5. A complete destruction of the pancreas did not result in either glycosuria or hyperglycaemia.

6 Various points in history, aetiology, and diagnosis have been referred to.

7. The observations are made from three cases of pancreatic cyst, though only one has been recorded in detail.

8. Attention has been directed to post-operative diabetes.

I desire to thank Dr. John Henderson, in whose wards two of the cases were treated, and Dr. R. Crawford for his radiological investigations. For the surgical work my thanks are due to Mr. Peter Paterson and Mr. George Stevenson.

TOTAL AVULSION OF THE SCALP

A NEW METHOD OF RESTORATION

BY

G. F. MITCHELL, M.D., CH.B.ABERD.,

SURGEON, HOSPITAL OF ST. CROSS, RUGBY

(With Special Plate)

Despite the careful supervision evident under modern factory conditions, total avulsion of the scalp occasionally takes place. One authority quotes 173 incidents in the literature[1] with eight deaths. The scalp was replaced in forty patients; in not one single case did the replaced scalp live. It is taught in some recent textbooks that a replaced scalp may survive, though it would seem that there is no ground for this statement, all the evidence pointing to the contrary. The most efficient method of treating this severe lesion has been by Thiersch grafts.[2] The patient later has to wear a wig, as the disfigurement is terrible. Attempts have been made to take Thiersch grafts from the shaven avulsed scalp, but however successful the operation has been in the past, there is no doubt the whole thing was looked upon as an inevitable compromise.

CASE RECORD

Bearing this in mind, I endeavoured to do something different in the following case.

A young girl, aged 16 years, was brought to hospital on June 21st, 1932, with complete ablation of the scalp, the

avulsed scalp being brought up in a sheet of newspaper. I postponed intervention for seven days, during which time the patient had completely recovered from shock and the initial haemorrhage: the affected area was clean, and granulations were spreading over the pericranium.

The method of restoration adopted was as follows. The denuded area, some six inches in diameter, and the remaining shaved scalp, were dressed in saline packs. Under full anaesthesia I made a series of incisions extending right down to the pericranium, three at the lateral and two on the anterior and posterior aspects (see Fig. A), the resulting flaps being

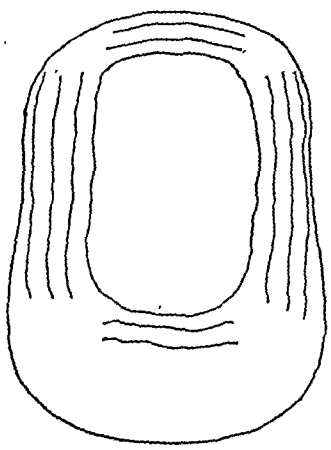

FIG. A

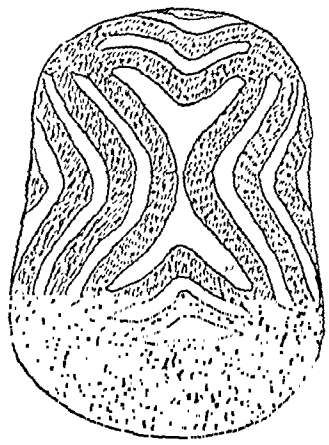

FIG. B

In Fig. A the avulsed area is reduced in size so that the lateral incisions may be shown.

some three-quarters of an inch wide. Care was taken to leave sufficient attachment at each end of the flaps to allow of an adequate blood supply. No attention was paid to haemorrhage, and each succeeding whole-thickness flap was undercut and levered towards the centre. The upper lateral flaps were first sutured together with strong catgut. The next lateral flaps were then sutured to the first, leaving a gap of half an inch, the third lateral flaps then sutured to the second, leaving another gap of half an inch. In the same way the anterior and posterior flaps were undercut, levered to the centre, and held by catgut sutures (see Fig. B). During this time the haemorrhage had been easily controlled by pressure. The whole operation area was then flushed with a 0.5 per cent. chlorine solution. A large sheet of oil silk soaked in liquid paraffin was spread over it, subsequent pressure being obtained by means of a capeline bandage. At the end of a week the flaps were firmly adherent to the pericranium.

Three weeks after the operation the centre gaps were rather wider than I had anticipated, but the granulations were healthy. Under full anaesthesia I therefore made two tongue flaps from the back of the scalp and turned them up into the adjacent gaps, after having removed the thick granulations. None of the hair-bearing scalp flaps was destroyed, and by October 11th the hair was growing well, the granulation areas being smooth and flush with the adjacent scalp. All bandages were removed at this time, the patient having mild doses of ultra-violet rays every second day.

A study of the photographs (see Plate) shows what progress has been made since the operation. The hair is now already long enough to dress back, so that the bare channels, which of course are inevitable, will shortly be entirely hidden.

OBSERVATIONS

The above method is without doubt an improvement on the Thiersch graft plan, which, however successful it may be, entails the wearing of a wig.

The actual operation takes little time, and the narrow channels between the flaps require no attention, the granulations filling the gaps completely.

The post-operative appearance is a source of satisfaction, because there is hair on the top of the head.

In nine months' time there will be no disfigurement.

I am indebted to my colleague Dr. W. Roche for his helpful suggestions.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

POST-OPERATIVE INTESTINAL OBSTRUCTION

The difficulties associated with the early diagnosis of intestinal obstruction following operation involving peritoneal drainage, and the problems consequent upon such a diagnosis, render any commentary and criticism of interest and of value.

S. D., aged 25, was admitted to the War Memorial Hospital with the diagnosis of perforated duodenal ulcer; the patient's history suggested a perforation of several hours' duration. At the operation that evening a perforation of a chronic ulcer of the first part of the duodenum was found. The perforation was closed, and reinforced by an omental graft; there was a moderate amount of peritoneal exudate, removed by water suction aspiration, and drainage established by a Greenwood tube to the pelvis, with a glove drain to the right kidney pouch. Fowler's position was adopted; drainage ceased after twenty-four hours, and drains were removed in thirty-six hours.

On the fourth day after operation the patient complained of upper abdominal discomfort, and vomited once. The bowels were opened by enema; pituitrin with eserine in small doses, with anti-gas-gangrene serum, was given. On the fifth day there was a return of abdominal discomfort, the patient vomiting twice; the general condition was satisfactory and abdominal examination negative. Enemas were repeated and serums given four-hourly. On the sixth day the patient's condition deteriorated; vomiting became of a faecal character, and there was persistent abdominal discomfort, with rising pulse. It was evident that a mechanical obstruction existed. Under local infiltration anaesthesia a small incision was made over the left upper rectus, the muscle was split, and a dilated coil of small gut secured; an enterostomy was made after the method of Witzel. While in the theatre drainage of several pints of a thin faecal fluid was effected, and three pints of normal saline were injected intravenously. Salines and ammonium chloride were given continuously per rectum. For the subsequent four days the enterostomy continued to drain; the general condition improved, and the tube was loosed on the fifth day. It was apparent an ileostomy had been performed.

On the eighth day after enterostomy, under open ether, the abdomen was opened by a sub-umbilical mid-line incision. The obstruction was in the form of a "matting" of a coil of lower ileum in the pelvis; the proximal bowel was rather dilated and turgid. A lateral anastomosis short-circuiting the obstruction was made. Haemorrhage was troublesome. That evening the patient's condition became unsatisfactory, and quantities of dark altered blood appeared from the enterostomy opening. It was suggested that haemorrhage from the site of anastomosis was proceeding. The abdomen was reopened, the line of anastomosis exposed by a vertical incision in the proximal loop parallel to the line of union, haemostasis secured, and the gut wall closed. Further intravenous hypertonic salines, with continuous rectal salines with glucose, were given. Subsequent progress was uneventful. The bowels opened normally, and the enterostomy opening, after continuing to discharge for some time, closed spontaneously. There was a rapid improvement in the general condition, and the patient was discharged fit.

The difficulties are associated mainly with the question of an early diagnosis. A condition of ileus existed on the third day, with a plastic peritonitis involving the lower ileum, and a final organization causing a definite mechanical obstruction. The state of the bowel at the time of enterostomy, and the character and quantity of the bowel contents drained, serve to emphasize the divergence of the clinical condition from the actual pathology.

Early exploration is essential, but such a course with a satisfactory general condition and on no other evidence

an elusive discomfort (relieved by an enema) and ional vomiting appears a bold one. The operation ıterostomy, with a short-circuiting operation at a date, seems a logical and proper procedure. The of abundant chlorides was demonstrated.

A. B. Davies, F.R.C.S.Ed.
Honorary Surgeon, Pembroke County
verfordwest. War Memorial Hospital.

BILATERAL SALIVARY CALCULUS

ıugh unilateral salivary calculus is common, we think following case worthy of record because it is of the teral type.

young man of 26 complained of a swelling of his neck, ch became appreciably larger whilst taking solid food. er examination the diagnosis of salivary calculus was made, an *x*-ray photograph taken to confirm this. The radiogph (by Dr. Rowden of Leeds) showed a condition of ıteral salivary calculus, with the right one larger and more ıterior than the left. The radiograph was taken with a ge intra-oral ball of cotton-wool and the mouth firmly sed over it. At operation Mr. B. Hughes removed the ht calculus by the external route, as it appeared embedded the gland. The left one was removed by the internal ute. On seeking further a third calculus was found in the t duct, and this was also removed. A large tonsil was ucleated.

The interesting feature of this case is the rarity of lateral calculus of the salivary gland. We have not een able to find any record of double stone, nor have the ırgeon and the radiologist in their long experience ever een a case.

UNILOCULAR CONGENITAL CYSTIC KIDNEY ASSOCIATED WITH SUDDEN DEATH DUE TO HEART DISEASE

When cystic kidneys occur they are generally multilocular. Unilocular cystic kidneys are so rare that the following notes of such a condition may be of interest.

A club steward, aged 42, complained one evening while carrying out his duties of a feeling of "tightness across the chest." He walked home, about a quarter of a mile, and, not feeling well, went to bed. His wife, on seeing her husband about twenty minutes later, sent for me. On my arrival I found he had been dead about half an hour. There was no history of his having complained of "tightness across the chest" previously. Two years before he had had follicular tonsillitis. I had attended him during that illness and had found no evidence of heart disease, nor did I feel anything abnormal in the left kidney region.

At the post-mortem both lungs were found to be congested but otherwise normal. On opening the pericardium some clear, coloured fluid was found; the cavities of the heart were empty. There were some fibrous nodules on the mitral valves, but not such as to cause incompetence. The aorta showed calcification of the walls, with "egg-shell crackling." The liver, spleen, and brain were normal. The right kidney and ureter were normal, but in place of the left kidney there was a rounded, calcified, unilocular cyst about the size of a cricket ball, the walls of which were composed of dense fibrous tissue, with a fibrous ureter leading away from it. The cyst was full of thick yellow fluid. The interior walls of the cyst had deposits of salts, forming hard, irregular patches. Cultures made from the interior showed the presence of very few micro-organisms. There was no trace of renal substance about the cyst.

Reports of Societies

CLIMATIC CONDITIONS AND INSECT POPULATIONS

At the December meeting of the Royal Society of Tropical Medicine and Hygiene, Dr. P. A. Buxton, in a paper on the effect of climatic conditions on populations of insects, said that the numbers of insects were altered by many different causes, chief among which were climate and an increase or decrease of their enemies and parasites. Seasonal changes in the insect population might be correlated with the incidence of certain diseases, such as the relation between rat fleas (*Xenopsylla cheopis*) and plague in rats and men in tropical countries, and between lice and relapsing fever in Northern India. Similarly, excess of winter rain in Mediterranean countries was followed by a marked increase in the number of anopheles and by outbreaks of malaria. Investigations might be conducted in either the field or the laboratory. Although field observations were a necessary preliminary, their function was to set problems which would subsequently be solved only in the laboratory, where experiments could be devised in which single factors varied. It was generally found that insects died after one hour at 104° to 113° F., or after an exposure of twenty-four hours between 95° and 104° F. In many parts of the Tropics the shade temperature exceeded these limits, and this was probably why insects became rare at particular seasons. On the other hand, while in the warm climates many insects existed at temperatures approximating to the fatal, they could survive temperatures many degrees below what they encountered in nature. Temperature factors often operated at critical points in the life-cycle, and so far as insects of medical importance were concerned, in no single species had these critical points all been determined. Furthermore, the velocity of insect development depended on temperature. Atmospheric humidity was another important factor, and recent advances in hygrometry had thrown new light on entomological problems. Insects might be divided into two classes—water "spenders" and water "savers." The former lived in moist environments, ate food of high water-content, and lost water readily in their excreta, etc. The latter lived in dry environments on dry food, and were resistant to starvation. The tsetse fly (*Glossina*) was obviously a "spender," depending on high atmospheric humidity; and the adults of Lucilia, Calliphora, and Trusca, and the larva of *X. cheopis* also came into this category. On the other hand, *Ornithodorus moubata*, the tick transmitting African relapsing fever, the adult *X. cheopis*, and the bugs Cimex and Rhodinius were "savers." A large insect placed in hot dry air might or might not regulate its body temperature by evaporation, but a small insect could not do this, and its existence depended on its being a "saver" or on having a high thermal death point. Martin and Bacot were the first observers to determine that the duration of life of a fasting insect (*X. cheopis*) was determined by saturation deficiency. Similarly the loss of certain insect eggs appeared to be dependent on this factor. Micro-climatic conditions and effects of humidity were discussed, and Dr. Buxton suggested that solar radiation might yet prove as important as temperature and humidity in controlling insect problems.

Dr. C. B. Williams, remarking that his work was concerned with agricultural more than with medical pests, said that the number of insects existing at any moment depended on birth rate, fertility, length of life, and death rate. Climate was concerned with every one of those factors, while in the death rate food supply and the incidence of parasites also operated. The number of parasites relative to living enemies tended to increase at a greater ratio than the pest increased. In field work the complexity of factors was enormous. Dr. W. R. Thompson said that, as long as it was impossible to predict coming meteorological conditions with certainty, it would remain difficult to put laboratory and physiological data into practice. Mr. Uvaroff stated that

insects survived in nature mainly on account of their tremendous ability to multiply and their short life-cycle, which enabled them to utilize even a short period of favourable environmental conditions. Knowledge must be obtained from two sources—namely, the climatic and micro-climatic conditions in the field, and the physiology of the insect itself. Major AUSTIN expressed the opinion that theoretical and experimental entomology was not so much of value in itself, as in the training it gave the entomologist to investigate problems and think rationally. The study in the field was most important. In Egypt the weather in the summer got too hot for flies to breed in stable manure, and theoretically they should have died out. Practically, however, it was found that artificial breeding places had been created by the Egyptian's fondness for water melons, the rinds of which were thrown out on the rubbish heaps of the city, fleshy side downwards, producing damp spots for breeding. In Russia horse flies had proved a terrible scourge, until in St. Petersburg Borchinski found that by covering the lakes with petroleum and so preventing their access to drinking water wholesale destruction followed.

Sir LEONARD ROGERS referred to his work in India, showing by charts how the incidence of plague decreased with a high temperature and high saturation deficiency: a marked difference existed in the various provinces. In the Deccan, plague began in the rainy season, and persisted through it, since the temperature was only 70° to 75°. Data for the Punjab, giving the saturation deficiency for four seasons of the year and the temperatures in the hot weather and rainy season, showed that a low saturation deficiency meant a high incidence of plague and a high saturation deficiency a low incidence. On the basis of such information forecasts could be made. Dr. WIGGLESWORTH pointed out that if a newly hatched bed bug was kept unfed in a dry atmosphere it lost water, but maintained its bulk by swallowing air; this distended the stomach, so that it might ultimately herniate into the femora, or rupture, producing surgical emphysema. If blood was now sucked up, the corpuscles escaped into the body cavity and could be observed there for as long as three weeks. Dr. HURST, discussing certain aspects of the flea problem in relation to plague, said that Dr. Buxton's observations on the climatology of burrows were of particular interest in regard to field rodent plague.

RESEARCH IN CONTRACEPTION

At a meeting of the London Association of the Medical Women's Federation, held at B.M.A. House on December 15th, 1932, with Professor LUCAS-KEENE, the president, in the chair, Mr. CECIL VOGE, Ph.D., read a paper on recent research in contraception. He described the results of three years' research which had been carried out in the Institute of Animal Genetics, Edinburgh University, on behalf of the National Committee on Maternal Health of New York. The outcome of the work had been the formation of a museum dealing with contraceptives in the department of public health of the university, and recently a similar one had been arranged in the same department of the London School of Hygiene and Tropical Medicine. Since there appeared to be evidence that woman would continue to regulate her reproductive life, it seemed to be the duty of the medical profession to ensure that the methods she used were harmless and efficient. The subject was divided into the following sections: (*a*) the scope of the research; (*b*) the anatomy of the reproductive organs, with special reference to their relation during coitus, and the fitting of mechanical contraceptives; (*c*) the effect of pure chemicals upon the life and vitality of the spermatozoa; (*d*) a study of vehicles for the suspension of spermicides; (*e*) a study of proprietary contraceptives, their quality, behaviour, and packing; (*f*) the chemistry of rubber; (*g*) summary. Dr. Voge expressed doubt whether one universally applicable contraceptive method could ever be found, but an attempt had been made to establish criteria for each type so that the medical man could choose a contraceptive suitable for a particular patient. He explained that although we had considerable knowledge of the success obtained with mechanical methods, little if anything was known of the effect of chemical ones used *per se*. The help of practitioners was asked in accumulating reliable data upon this point, which would seem, in view of the sales of these products, to be relatively easy to obtain. Dr. Voge said that he had recently approached certain members of the contraceptive trade with a view to their setting up for themselves certain standards of manufacture, packing, and distribution. He reported that they welcomed a move in this direction and said he could rely on their support. He invited members interested in this difficult subject to visit the museum.

GENETICS IN MEDICINE

At the last meeting of the London Jewish Hospital Medical Society, Professor LANCELOT HOGBEN delivered the annual oration of the society on the medical application of genetic principles.

Professor Hogben dealt with recent progress in the application of Mendelian analysis to clinical conditions in human beings. He outlined the different methods which had been devised to surmount the difficulties arising from the facts that the human family is small, and that the clinical geneticist cannot arrange the matings of the organism he studies. Special importance, he emphasized, was to be attached to the study of consanguineous unions as a means of detecting clinical entities determined by single recessive Mendelian factors. With large-scale investigations on such lines a fruitful harvest might be expected. Alcaptonuria, retinitis pigmentosa, xeroderma, and amaurotic family idiocy were quoted as examples of conditions which had been subjected to the most rigorous genetic analysis. The inherent obstacle to such analysis, arising from the tendency to place on record cases illustrating a high familial incidence, while neglecting records of families with isolated cases, was discussed. The speaker then considered the practical consequences of sterilization. He showed how the magnitude of the result depended upon the kind of transmission involved, and indicated the kind of prognosis which was possible when the mode of transmission was established. A distinction was drawn between the analysis of discrete characteristics such as the "hereditary" and "familial" diseases, and the problem of assigning the part played by hereditary factors in highly variable characteristics such as disease resistance and intelligence measurements. Recent evidence from the study of twin resemblance was discussed in relation to the common and unfounded assumption that differences of the intelligence quotient were mainly determined by genetic factors. Professor Hogben drew attention also to the need for distinguishing between the role of nature and nurture in determining variations within the family, on the one hand, as opposed to variations between individuals belonging to different families at different social levels on the other.

THE FUTURE OF SURGERY

At the last meeting of the Manchester Medical Society Mr. V. Z. COPE read a paper entitled "The future of surgery."

Mr. Cope said that the last fifty years had seen an altogether unparalleled development of surgery. Surgery had advanced almost as far as possible along anatomical lines. There was no region of the body immune to the surgeon's attack. In the future, advance must come from diagnostic and technical improvements and physiological and pathological researches. Of the three great obstacles to surgical work—haemorrhage, shock, and infection—the first had lost most of its terrors since the introduction of blood transfusion. Infection was not feared in surgical wounds, but the problem of established infection remained. As yet there was no reliable method of getting rid of infection which had established itself in the tissues. In the future it was to be hoped that there would be found some antiseptic which, after intravenous injection, would get rid of this type of infection—especially when caused by the streptococcus. Lately, new methods of

olling infection had been discovered. The cure of tion of the renal tract caused by the *B. coli communis* eeping the patient on a ketogenic diet, opened up a of possibilities. It was quite likely that modifica- of diet might play a greater part in the control of y surgical diseases. Much work remained to be done urgical shock. It was to be hoped that a broader of the pathology and symptomatology of this con- on would be adopted. Sufficient account had not yet taken of the element of shock caused by the absorp- of the products of disintegration of tissues. Surgery ld be greatly advanced when an antidote was found these toxic histamine-like bodies. Latent shock also ded to be more widely recognized.

he future was bound to see a great increase in what ht be called preventive surgery. The removal of eased tonsils had almost led to the disappearance of erculous glands in the neck. Gummata were now ely seen. Rickety deformities were much rarer. The ly treatment of hernia by operation should prevent angulation. Possibly the population might consent to annual inspection to detect any condition needing gical treatment. The technique of surgery would im- ve by the devising of various instruments and the provement of electro-surgical devices. Radium would ver entirely replace cutting surgery unless the technique application was greatly improved. *X* rays were likely play a much larger part in the treatment of malignant sease than they had hitherto played.

As to the future status of the surgeon it was difficult to recast. The number of well-qualified surgeons was in- easing and likely to increase. Decentralization was roceeding rapidly, and specialization was increasing. The pecialist should be a research worker, who ought to tandardize his craft for general use. In the future there would most likely be a better co-ordination between the maller cottage hospitals and the larger city hospitals, which would probably play the part taken by base hospitals in wartime. Voluntary hospitals were now having pay-beds attached to them, and in the future this endency would increase until most of a surgeon's work would be done in hospitals or similar institutions. The municipal and council hospitals would play a larger part in the surgical service of the future, and attract many of the junior surgeons. A full-time civilian surgical service was a probability of the future, but there would always be room for surgeons of ability who preferred to keep their independence.

INCAPACITY IN INDUSTRIAL INJURIES

At a meeting of the Liverpool Medical Institution on December 15th, 1932, with the president, Professor R. E. KELLY, in the chair, Dr. H. E. MOORE (of the L. M. and S. Railway Company) opened a discussion on "The avoidable wastage resulting from industrial injuries."

Dr. Moore pleaded for a thorough investigation of the management of traumatic conditions with a view to the reduction of the great amount of avoidable wastage which existed as the result either of bad or ineffective treatment, or, in some cases, of entire absence of real treatment. He confined his remarks for the most part to the defects in treatment carried out, after the initial stage had passed, by the hospitals and the National Health Insurance. He said that the material which had passed through his hands suggested there was ample room for the investigation of that stage. Dr. Moore produced figures showing the enormous incapacity periods, in many cases for months, among men for whom all active treatment had ceased, and whom it had been possible to return to their former occupations after very brief periods of real active therapy. He argued from this that, with proper methods at an early stage, this wastage should not have occurred. As regards the hospitals, treatment was not sufficiently intensive or persistent. Passive measures in the form of massage, etc., were in many cases a pure waste of time and energy, and the co-operation of the patient in active treatment, which was the biggest factor towards recovery, was generally neglected. Surgical supervision, which was so necessary to give the stimulus and confidence leading to co-operation, was too spasmodic to be effective. Men were discharged before real proof of function had been obtained, and the mental factor present in all and prominent in many was usually ignored. As regards National Health Insurance, he stated his belief, as the result of the evidence supplied by his patients, that there was no active treatment available for the many men who needed such help to obtain recovery, and that under the present conditions of panel practice such treatment was not possible. He urged that both the hospitals and the National Health Insurance, which received such large contributions from industry, should give this problem their serious attention with a view to the formation of some service which would reduce the present colossal wastage. The remedy appeared to him to be the complete separation of the traumatic cases from the ordinary work of the general hospitals; the establishment of traumatic centres throughout the country, with specially trained resident personnel, controlled by orthopaedic surgeons who had made a specialty of this class of work; and free facilities for treatment in these centres for all panel patients who were proving resistant or who required active treatment.

Mr. R. WATSON JONES agreed with Dr. Moore that far too few workmen recovered so completely from industrial injury as to be capable of early and full re-employment, and said that the "traumatic" surgeon should solve the problem primarily by raising the standard of fracture treatment and by remaining satisfied with no result other than that of a limb indistinguishable from normal. Too often in the past minor degrees of angulation, slight displacements, and the lesser degrees of shortening had been accepted as quite satisfactory results, and only too frequently periarticular adhesions, lateral instability of joints, hypotonicity of muscles, and recurring swelling of limbs had been entirely overlooked. The limb which was indistinguishable from normal could be secured in the great majority of fractures by conservative methods, provided that the surgeon relied on *x*-ray control after reduction, and showed a greater willingness to remanipulate, when necessary, a second or a third time. It was equally important that disuse changes in muscles, joints, and circulation should be anticipated and prevented by early functional activity. Few workmen deliberately malingered in the early days of an injury solely with the object of making money. On the other hand, if minor disabilities were allowed to remain, no workman could be blamed for fearing that his incapacity might increase with the strains of work, or that his incapacity, however slight, might lead to his early discharge on the grounds of inefficiency. The exaggeration and malingering which were the outcome could be avoided by achieving more perfect results. Traumatic neurasthenia and other functional disturbances were also frequently to be regarded as avoidable complications of industrial injury. They were due to excessive hospitalization, or to the adoption of passive methods of treatment such as massage, splints, and apparatus, in place of exercises practised by the man himself, or, better still, of occupational activity from the early days of the injury.

Mr. BRYAN MCFARLAND put forward the following points. (1) Segregation of fracture cases was not a complete remedy for the wastage. With minor injuries it was essential to maintain close liaison with a general hospital. It was often the cases with trivial injuries in which there was delay in returning to full work. Moreover, team-work was essential in dealing with patients who might sustain damage to an eye, a spleen, or a femur. (2) Until some ideal scheme, such as suggested at Alder Hey was organized, much could be done at once by close co-operation between the employers and the surgeon responsible. If an employer would communicate with the surgeon immediately and would work with him, there would be none of the gaps which Dr. Moore had shown to be the cause of wastage. Thus, the legal implications would be avoided; for, whatever might be said to the contrary, the thought of possible compensation for their injury was immediately present in the minds of certain men, and once they had "started proceedings" a cure

was unattainable. Even when cured, how could they be proved fit for work? In Liverpool it seemed to be increasingly difficult to prove that a fit man was fit. With adequate early collaboration of surgeon and employer such proceedings would be "short-circuited." Mr. McFarland's experience at the David Lewis Northern Hospital was that those firms who "carry their own insurance" co-operated most effectively and with a minimum of wastage; whereas any attempt to obtain the co-operation of an insured firm to curtail the unemployable period or to reduce ultimate disability was met with the reply, "We are insured"; and from the insurance company, the apathetic reply, "We are covered."

Dr. J. BERKSON said that just as payment for sickness and payment for claims under the Workmen's Compensation Act were separated, so should the treatment of industrial injuries be separated from the treatment of ordinary illness. Patients with industrial injuries and having massage came to their panel doctor for a certificate of incapacity, and when he wished to sign them off as fit he was told that the patient had to go back to the out-patient department in four weeks' time, and therefore was not fit to start work. In some cases that went on for months. If the panel practitioner was not allowed to give certificates of incapacity when his patient was attending for treatment at hospital one quite important cause of wastage would be got rid of. Mr. RICHARD BICKERTON said that the discussion was proof of the interest now taken in preventive medicine. Employers should not be asked to shoulder any more financial burdens until the profession was satisfied that they were getting full value for the money they were now contributing to the health services of the country. In some districts much had been done to lower the cost of litigation under the Workmen's Compensation Act without hardship to the disputants, and he urged medical men to co-operate with him with this end in view. The junior men at the Bar might oppose it, but he knew that the senior men would support the medical profession. Many cases as conducted to-day only brought discredit on the medical witnesses and injustice to the genuine workmen. Previous speakers had indicated the lines on which the present medical services could be organized so that much human wastage might be avoided, and he hoped that the Liverpool Medical Institution would formulate a plan. The members not only had the knowledge but the ability to do this necessary piece of work. Dr. K. COBBAN, speaking as a general practitioner in a mining district where there were many accidents, said it had been his experience that the majority of patients were eager to get back to work. With regard to the treatment of the long-standing cases he did not think that it could be carried out by the general practitioner, but necessitated attendance at hospital; nor did he think that the usual massage treatment carried out at present was efficacious. He would advocate its replacement to a large extent by active movements of the injured parts, and especially by curative workshops.

CHOLESTEROL METABOLISM

At a meeting of the Pathological Society of Manchester on December 14th, 1932, Dr. W. W. KAY briefly reviewed recent work on cholesterol metabolism. Endogenous synthesis of cholesterol by all animals appeared certain, but omnivores and carnivores had exogenous supplies as well. Cholesterol had no chemical relationship with either fats or lipins, but was structurally related to the bile acids, which were necessary for the proper absorption of fats and cholesterol from the alimentary tract. Although cholesterol was readily absorbed by animals, plant sterols, and the reduced forms of cholesterol, coprosterol, and dihydrocholesterol were not absorbed. Ergosterol, however, after irradiation, which produced molecular changes, probably steric rearrangement, became absorbable. Cholesterol excreted in the bile was largely reabsorbed, or might be converted to coprosterol in the intestines and excreted as such. Dihydrocholesterol seemed to be formed in tissues and excreted by the bowel wall. The normal ranges of plasma cholesterol and cholesterol ester were discussed, and their relations to diet and pregnancy. Variations in disease were also indicated. At present there was little to show the real function of cholesterol in health and disease.

PREMEDICATION

At the last meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, Dr. R. W. SHAW read a paper on premedication with nembutal. This drug, one of the newer barbituric acid derivatives, was first used by Lundy of the Mayo Clinic in 1929, and introduced to Europe by Magill in 1930. It could be administered orally, intravenously, or rectally, and was now preferred to the other members of the group—namely, sodium amytal and pernocton. The use of this drug was a big advance in securing the comfort of the patient, and in abolishing the more unpleasant effects of induction by the usual methods. Patients fell asleep peacefully and rapidly, and generally had complete amnesia for the day of operation. The dosage varied, but in no circumstances must it exceed 7.5 grains; the usual intravenous dose was about 6 grains, while orally 4.5 to 6 grains might be given. Any secondary anaesthetic might be used after nembutal, the most usual being ether; the quantity required was always considerably less after premedication, and the administration of nitrous-oxide-oxygen was much simpler and more satisfactory, especially for abdominal work.

Dr. R. W. SHAW reported a series of seventy-one cases. Nembutal was given orally in eighteen of these and intravenously in fifty-three. The secondary anaesthetics used were ether, chloroform, CE_2 mixture, nitrous-oxide-oxygen, and in four cases nembutal by the mouth was followed by spinal anaesthesia. Two cases were reckoned as failures. The advantages of nembutal over other basal anaesthetics were the ease with which it could be used, the rapid transition into unconsciousness, and the less unpleasant after-effects. In the series under review twenty-six patients vomited, eight developed a cough but only two ran temperatures, seven had slight headache which did not persist, fifteen were restless but only eleven required morphine. In conclusion, stress was laid on the need for an experienced administrator when the drug was used.

The President (Mr. HENRY STOKES) said that he had used nembutal in various cases and had seen it used in many others, and it seemed to him to be very good. Mr. F. J. MORRIN had used it extensively, and regarded it as extremely good. There were, however, certain cases in which it should not be employed, such as toxic goitre and jaundice. He had found that if a patient was given a large dose of luminal an hour to an hour and a half before operation, spinal anaesthesia was much easier to administer. Dr. G. P. MELDON said that since beginning to use nembutal in March, 1931, he had had a good deal of experience with it. One advantage was that it was burned up in the body and not excreted. The fall in blood pressure reached its maximum in about fifteen minutes, and then passed off. The fall was usually only about 15 mm. Hg, but in patients with very high blood pressures it would come down a little more. He had given nembutal in many cases which were not good anaesthetic risks, and had never been sorry for doing so. It should be administered very slowly. No barbiturates were really anaesthetics; they were only aids to anaesthesia.

Mr. H. MEADE said that he had had very good results from the use of sodium amytal. Dr. NINIAN FALKINER had used nembutal in some cases, and had noticed the relative absence of post-operative sickness and pain. The patients, however, were certainly more restless than after ether and gas. Dr. SHAW, in reply, agreed that nembutal should be given slowly. He had given it in only two obstetric cases, but the results had been very satisfactory.

Reviews

LABBÉ ON DIABETES

French excel as essayists and MARCEL LABBÉ is [illegible] interesting reading on diabetes. His present [illegible]ons Cliniques sur le Diabète,[1] like most of his books articles, follow the style of an essayist, where wisdom ideas have to be garnered quietly and slowly by [illegible] reading. His writings may be the despair of [illegible]se who would read quickly and wish to gather and [illegible]ize his facts from tables, classifications, and summaries. This cannot be done. But none the less the [illegible]ts and ideas are there, and should be read by all who [illegible] profoundly interested in diabetes and can find time prolonged study. This book is useful for every [illegible]ect of diabetes except concise practical directions. [illegible]rofessor Labbé covers a very wide field in his dis[illegible]n Little time is devoted to routine treatment, t most of the special features are dealt with at length. [illegible]ese chapters are devoted to diabetes in children, to berculosis, to gangrene, to coma—both insulin coma and [illegible]etic coma. Many of these sections have appeared various medical journals in exactly the same form as [illegible]ey appear in this book, which cannot therefore be said contain anything new. Most subjects are treated in an [illegible]teresting way in the form of a clinical lecture. Generly the problem is first defined, the existing knowledge [illegible]viewed, a few cases presented in considerable detail, [illegible]d the conclusions set forth. The latter are sometimes [illegible]ther vague, but hardly appear so until the author's [illegible]ofty dialectic presentation is submitted to critical [illegible]nalysis. Two chapters deal with two cases showing a [illegible]ombination of diabetes, cirrhosis of the liver, and testicular atrophy, and this has been called the " syndrome épato-pancréato-génital." One of these patients suffered [illegible]om bronzed diabetes, the other had no pigmentation. [illegible]he time of onset of the testicular atrophy was not [illegible]learly defined and may have been the result of the unreated diabetes, a well-known consequence. Both these [illegible]s responded easily to insulin, and altogether no facts [illegible]re presented which warrant the description of a new [illegible]yndrome. Professor Labbé has tried the administration [illegible]f insulin in all sorts of ways and finds the best to be the usual aqueous solution. The keynote of the book is a [illegible]ulogy of insulin.

OTOLOGY FOR OTOLOGISTS

" When a new book comes out, read an old one." According to Mr. Augustine Birrell this was the cynical advice once offered by a surly critic. The appearance of *The Principles and Practice of Otology*,[2] by F. W. WATKYN-THOMAS and A. LOWNDES YATES, recalls this dictum, though not in the derogatory sense in which its author intended. It applies in a different and perhaps more subtle way, for without a study of the older standard works it would be impossible for the beginner in otology to realize the revolutionary character of this book. It might easily fall into the hands of such a one, for the authors expressly state that they have written to help candidates for the D.L.O. That the authors have produced a scientific book full of fresh and stimulating ideas for the trained otologist is beyond question, though whether they will prove true friends to candidates at examinations nothing but the results will show.

It is to the scientific side of otology that the book is really devoted. The section on the properties and use of tuning forks, studied by the application of the half intensity period, is an example of how a proper training and the ability to apply mathematical principles has produced order and understanding from the chaos in which the hearing tests have long been sunk. The great reproach to otology has for long been the inability to benefit most forms of deafness, and the consequent neglect to study the cardinal symptom in otology, which until recently has flourished only in the surgical treatment of suppuration. The authors' views on the nature of deafness, the manner of its production, how its treatment should be managed, and how aids to hearing should be employed show originality based on a vast amount of careful work and observation. Where suppuration is concerned they follow the well-established lines and attempt nothing original, but even more importance is attached to myringotomy and its results than most aural surgeons would be prepared to allow. The orthodox character of this part forms a surprising contrast to the earlier sections. It seems almost too orthodox when the authors are found advocating the removal of every particle of clot in sinus thrombosis and describing severe operations on the jugular bulb, operations firmly lodged in the old textbooks but as obsolete as lateral lithotomy, while the importance of Alexander's method of treating the jugular vein is ignored. This part ends with a section on ligature of the *external* jugular vein. This would scarcely be worth mentioning if it were not one of many small errors, misprints, and mistakes in spelling which form a serious blemish to the book. However, the authors commit a much graver literary offence, for which they actually take credit in the preface. In the bibliography at the end of each chapter they give many references to abstracts of papers instead of to the originals, ostensibly for the convenience of students. They have, no doubt, themselves consulted the originals whenever accessible, but the originals should in all cases have been cited, followed by the reference to the abstract. As the authors do not recognize the ordinary rules of literary composition forgiveness for this must be included in a more general dispensation which allows that their book contains a most valuable account of recent research in otology, and provides a rich and abundant feast for the thoughtful. It is the established otologist who should read it and not the student, for it should not be attempted until Politzer, Ballance, Gray, and Milligan have first been mastered.

IRREGULAR PRACTICE

The Legal and Ethical Aspects of Medical Quackery[3] is a short but interesting book. The author, Mr. LE MARCHANT MINTY is not a medical man, but a barrister with experience of the law as it relates to medical men and to unqualified practitioners of the healing art. His publishers state that he has appeared on behalf of practitioners before the General Medical Council and has also been engaged in prosecution of unqualified practitioners. He views the problems he considers from a legal rather than from a medical aspect, and the scope of the work can most easily be indicated by the title headings of a few chapters: Infamous conduct in a professional respect ; Bogus practitioners ; The bone-setter ; The chiropractor ; The osteopath ; The abortioner ; Patent medicine quackery ; Religious quackery. This short list is a sufficient indication of the number of thorny questions which the author essays to handle in a volume of 260 pages.

[1] *Leçons Cliniques sur le Diabète.* Par Marcel Labbé. Paris: Masson et Cie. 1932. (Pp. 334 ; 36 figures. 40 fr.)

[2] *The Principles and Practice of Otology.* By F. W. Watkyn-Thomas, F.R.C.S., B.Ch., and A. Lowndes Yates, *M.C.*, M.D., F.R.C.S. London: H. K. Lewis and Co., Ltd. 1932. (Pp. xii + 568 ; 199 figures (5 coloured). 25s. net.)

[3] *The Legal and Ethical Aspects of Medical Quackery.* By Leonard Le Marchant Minty, Ph.D., B.Sc., B.Com., LL.B. London: W. Heinemann (Medical Books) Ltd. 1932. (Pp. xviii + 262. 7s. 6d. net.)

He starts with a critical discussion of the legal powers of the General Medical Council, and his main conclusion is:

"What is wanted is a new Medical Act which will give ample disciplinary powers, but at the same time provide for them to be exercised under the same rules of natural fairness and justice, governing procedure and evidence, as adopted in our law courts."

In this chapter there are certain passages that should be revised. Thus, when describing the disabilities suffered by an unregistered practitioner, the author (p. 23) states that orders made under the Dangerous Drugs Acts include "all the recognized anaesthesia" and that the Therapeutic Substances Act precludes such persons from being in possession of the substances to which it applies. The Dangerous Drugs Acts are, however, concerned solely with drugs of addiction, while the Therapeutic Substances Act regulates the manufacture of certain drugs and does not restrict their purchase. The remainder of the book deals chiefly with quackery, and in this connexion it is interesting to learn that Lord Loreburn in 1908 ruled in the House of Lords that the term "quack" meant not only a pretender to skill which was not possessed but also a person who, however skilled, lent himself to medical imposture. The account of the doings of quacks and unqualified practitioners is full of amusing anecdotes, and also contains much interesting information. The extreme tenderness that the law shows to quack medicine vendors is notorious, but it will surprise most practitioners to learn that

"Even if the name of a well-known living practitioner is made use of to lend colour to the claims of a patent medicine, he having in no way countenanced its use, there is very little he can do to stop it, save to give the facts publicity."

On the other hand, it appears to be actionable to depict a well-known athlete eating a particular brand of chocolate. Abortion presents another amazing contrast, for the police prosecute abortionists with rigour, but make no attempt to restrict the sale of "female weakness pills," which are advertised to "correct all irregularities," even though in some cases the vendors mention that the drugs in certain circumstances are likely to produce abortion.

The chief impression left by perusal of the book is that in medical matters the law of this country is chaotic. The book is short, very readable, and highly controversial. All medical men will find it of interest, although most will find points on which they differ from the author, and there are a number of small errors which careful proof-reading by experienced medical collaborators would have rectified. Apart from misspellings, such as "cocoa wine" and "flour or herb," the author's knowledge of professional customs is here and there out of date or otherwise at fault.

RADIOLOGY IN PAEDIATRICS

Professor ST. ENGEL and Dr. L. SCHALL have edited a very important Handbook on Röntgen Diagnosis and Therapy in Childhood,[4] which, with its wealth of illustrations (well over six hundred), will prove a valuable work of reference to all those concerned with diseases of childhood. The bulk of the book is concerned with diagnosis, while nearly two hundred pages at the end are devoted to treatment. Each section is the work of an expert, and the editors, while taking part in much of the text, have also been responsible for a skilful welding together of the various contributions to form an excellent whole. A good impression is gained early in a study of the book by a series of diagrams dealing with the ages of ossification, and that on page 33 (a composite diagram) will make lungs are very well done, and a series of beautiful *x*-ray pictures are supplemented by line drawings and photographs of pathological specimens. The radiology of the heart in childhood is approached in a thoroughly scientific manner, and indeed the mathematics strewn about this section, especially in relation to "surface quotients," make very complex reading. The pictures in the section on encephalography are really striking in the wealth of detail revealed, but in the adjoining chapters on the skull bones the paragraphs dealing with the nasal sinuses are disappointingly brief and poorly illustrated. Extensive bibliographies make the book valuable for reference, and there are very full indexes to subjects and authors.

The main impression left from a detailed perusal of this volume is that paediatrics in our own country is not making nearly enough use of *x* rays, and perhaps this feeling of envy may lead to some radical progress. Certainly the standards set by St. Engel and Schall will take a lot of reaching. The illustrations are throughout reproduced in the body of the text, and the price for this style of production does not seem unreasonable.

A SHORTER ORTHOPAEDIC SURGERY

Under this title Mr. R. BROOKE of Worthing has put forth a book[5] which, as he states in his preface, has been written at the suggestion of the masseuses attached to the orthopaedic department of the Royal West Sussex Hospital, whose work lies at a distance from the hospital and does not allow them to attend often and become as familiar as they could wish with the operative and other treatment of their cases. In undertaking to supply their wants and those of house-surgeons and other residents Mr. Brooke has imposed upon himself a difficult task, for we take it that condensation in such a subject involves great skill and discrimination. In the given circumstances the most that can be aimed at is a clear statement of general principles, leaving the details of treatment to personal instruction and example and the larger manuals. We think the author has succeeded in fulfilling his purpose; and in one particular direction he has gone much further, for in the article on flat-foot the relief of that common deformity is discussed in considerable and useful detail.

THE SOUTH-WESTERN BRANCH OF THE B.M.A.

There has recently been published, by direction of its Branch Council, a history of the South-Western Branch of the Association.[6] This, formed in 1840, was the fourth Branch in the history of the Association, the East Anglian (1835), Bath (1836), and Lancashire and Cheshire (1837) having preceded it. The sterling part played by the Branches in the development of the Association, and the subsequent conflict between the Branches and the Central, perhaps too central, Council has been fully described by Dr. McVail in his articles in the *British Medical Journal* in 1924, and by Mr. Muirhead Little in the "Centenary History." Suffice it to say here that our present democratic constitution, with meetings so organized that every member in the Kingdom has the opportunity of attending one and that every such meeting sends a delegate to instruct the executive of the central organization as to its public actions during the following year, has been the ultimate result.

[5] *A Shorter Orthopaedic Surgery.* By R. Brooke, M.S., F.R.C.S. Bristol: J. Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1932. (Pp. 150; 126 figures. 10s. 6d. net.)

This little history is a model showing what an active ...ch can do, not only for the protection of its own ...bers—as, for instance, action in the matter of vaccin... fees, troubles with nurses and midwives, hospital ..., coroners' courts, life insurance fees, workmen's ...mpensation—but also in scientific work, its post-...duate courses at the two big hospitals at Exeter and ...lymouth, its quarterly scientific meetings, and its public ...ps to improve early recognition of cancer. There also ...erges what a Branch can do to stimulate the whole ...ssociation. From 1858 to 1902 the South-Western Branch ...ok a most active part in the question of the Medical ...cts and medical education, even sending a memorial to ...rd Palmerston, and persuading its local members of ...Parliament to secure amendments in the Association's own ...ill. It sent Dr. William Gordon to be the prime mover in ...he reform of the Army Medical Services, leading to its ...ecognition as a Royal Corps in 1902. The mention of ...ordon brings out how much our local Branches and ...Divisions depend for their activity on personalities, in which the South-Western Branch has been so fortunate. We read of Thomas Shapter, John Haddy James, Samuel Barnes, Henry Davy, Maury Deas, Roper (the present president, son and grandson of former presidents), and last, but the reverse of least, the author of this history, "Russell Coombe of Exeter." As might be expected, his name hardly appears in this booklet, but to those who know, it is largely due to him during the last thirty years that the South-Western Branch has kept up its old tradition and activities. To the list of his splendid achievements for the Association, recognized by his election as a vice-president in the centenary year, may fittingly be added this History, his latest "labour of love" for his Branch and the Association.

Notes on Books

As the author, Professor STERLING V. MEAD, justly says, in his preface to the latest edition of his work on *Diseases of the Mouth*,[1] the fact that this book has reached the fourth edition in so short a time proves that there is a widespread and increasing interest in the subject. We think the author might take to himself more of the credit for this increased interest. Throughout the book special attention is given to diagnosis, and every disease and every aid to diagnosis is fully illustrated (nearly 200 new photographs have been added to this edition), in the hope that early diagnosis will lead to more prompt and efficient treatment. The work is a record of unremitting clinical observation, and very few mouth conditions have escaped the author's personal notice. The chapter on stomatitis is a good example of his thoroughness, and we think the notes and illustrations of "medicamentous eruptions" of particular interest. In so practical a book we should like to see a fuller account of tetanus: chronic tetanus receives a bare mention, and local tetanus is unnoticed. There are upwards of 500 excellently reproduced illustrations.

Following on *Blenheim*, Professor TREVELYAN has published his second book dealing with England under Queen Anne. *Ramillies and the Union with Scotland*[2] forms a continuation of the first volume, and embraces the period 1705–9. In his preface the author tells us "it is a rope twisted of three strands: the war, English politics, and the Scottish problem." A vivid picture is given of Marlborough at the apex of his career, beginning with the decisive victory of Ramillies in 1706. His brilliance as a tactician and his military genius are clearly shown in the simple yet graphic accounts of the tragedy of our Peninsular war, the taking of Barcelona, and the gallant defence of Gibraltar. There are no digressions from the main point, no incomprehensible and unnecessary technicalities. Professor Trevelyan has also achieved what may well be Marlborough's final vindication from the many tales of "meanness, avarice, and treachery" started as a Tory vendetta and given credence to by Macaulay in the nineteenth century. At home we find Queen Anne striving to fulfil her duties as sovereign, but handicapped by ill-health and the endless intrigues and dissensions between "those enormous vile factions" the Whigs and Tories of the Godolphin Ministry. The condition of Scotland before the Union is vividly depicted. Poverty, sickness, political and religious quarrels, were rife throughout the whole country; yet in not one whit did the Scot consider himself the inferior of his despised neighbour "the auld enemy," to whom he applied the disparaging epithet of "porkeater." However, there were level heads on both sides—Marlborough, Godolphin, Somers, and Hardy for England, Queensberry and Argyll for Scotland—and "their action was based not on theory, but on sound information." Thanks to their insistence on the spirit of prudent compromise the Union of the Scottish and English Parliaments was achieved, forming a part of the scheme on which the British Constitution has rested ever since. The author displays great accuracy and is impartial in his judgements. What he says he gives a good reason for saying. *Ramillies* is a book which will prove of inestimable value to the student, while the facts are so clearly stated and so charmingly told that it is also bound to interest the average reader.

In his work on Cutaneous and Sexual Diseases,[3] which forms the thirteenth volume of Lehmann's series of medical textbooks, Professor L. R. v. ZUMBUSCH, director of the dermatological clinic of Munich University, has admirably succeeded in his purpose of giving practitioners and students a concise and clear account of the essential clinical and pathological features of the subject. The book is divided into two parts. The first or general part consists of eleven pages dealing with the anatomy and functions of the skin, the general diagnosis of skin diseases, their localization and aetiology; while the second part, which forms the bulk of the work, consists of a systematic account of the various skin diseases, followed by a description of syphilis, gonorrhoea, chancroid, and other diseases of the external genitals. In view of the fact that many of the photographs in dermatological textbooks do not really fulfil their purpose, the absence of any illustrations does not detract from the value of the work.

There is much practical wisdom to be found in the pages of Dr. NEUBERGER's handbook on mental diseases, which bears the title *Comment diagnostiquer comment traiter les maladies mentales*.[10] Of necessity the counsel given as to the disposal of certain patients whose conduct has rendered them unfit to be at large can only be of academic interest in this country; but apart from such differences of procedure this manual contains so succinct an account of the various mental disorders, the mode of their detection, and the therapeutic measures employed, as to make it serviceable to all who are acquainted with the French language. The author insists on the necessity of a systematic interrogation of his patients, and warns his readers of the danger of allowing this to degenerate into a mere conversation in which certain supposedly unnecessary questions have not been posited. The constitutional predispositions are carefully depicted, while the descriptions of the individual psychoses leave nothing of importance unsaid. It is interesting to note that mania and melancholia are contrasted primarily in respect of excitement as against inhibition. Probably it is more general in this country to regard the elation and the depression as the fundamental features of such states, which allows one to speak of a "passive" mania or an "active" melancholia. The book is prefaced by a forcible introduction from the pen of Dr. Fiessinger.

THERAPEUTICS IN 1932

A review of therapeutic progress during the past year must, from considerations of space alone, be incomplete, and, since time and wide experience are necessary to prove the value of new remedies and methods, an annual survey cannot pretend to give decisive judgements upon them. Here, then, it is only possible to set out, in somewhat telegraphic form, a few of the things that have been done. We cannot attempt to give a world-wide or even a European survey of therapeutics. What follows mainly relates to France. Not because France is considered to hold the *cordon bleu* in therapeutics, but because this will enable our readers to form some idea of the " therapeutic attitude " of a body of physicians trained in a different way and with a different national tradition behind them. For this we are largely indebted to Dr. P. Harvier's admirable survey, in the *Paris Médical* for December 3rd, 1932, of original and interesting work published during the year. Readers may be referred to that journal for much of the material upon which our commentary is based.

Dealing with the treatment of infections an important monograph is noted, which comes from the Pasteur Institute, on preventive vaccination for tuberculosis in man and animals by B.C.G. This is a collection of forty-six reports from various countries, excluding France, giving the results of several years' observation of various groups of infants brought up under identical conditions of contact with tuberculous infection. Some of these infants were vaccinated with B.C.G. and others were unvaccinated. It is claimed that these reports demonstrate once again the harmlessness of the method and its efficacy in diminishing the mortality from tuberculosis. Recent reports of the results of active immunization against diphtheria go to show that the success of this method is becoming year by year more striking. One author advises the systematic inoculation of infants with a mixture of anti-variolous and anti-diphtheritic vaccine. The increasing efficacy of serotherapy in streptococcal infections is generally admitted, and it is to be hoped that before long streptococcal infections, even the haemolytic types, may be robbed of their terrors. *B. coli* infections apparently yield excellent results under treatment by the serum of Vincent. Two new methods have been introduced for the control of serum reactions—namely, the oral administration of pancreatin, both as a prophylactic and for relief of symptoms which have developed, and the combined administration of sodium benzoate and salicylate. Various French writers emphasize the value of vaccinotherapy in the treatment of typhoid and paratyphoid fevers. An interesting critical review of different methods of treating erysipelas has recently been published by Schachter. Tetanus has been treated with remarkable success by intravenous injection of serum combined with urotropine. It is suggested that the urotropine facilitates the entrance of the antitoxin into the cerebro-spinal fluid. Post-vaccinal encephalitis seems amenable to intraspinal, intravenous, and intramuscular injections of serum from individuals who have recently been successfully vaccinated. Béclère, however, prefers the serum of a vaccinated heifer, believing that this serum preserves its " antivirus " properties indefinitely, while the human serum fails to do so. For immunization against poliomyelitis Pettit has prepared a horse serum which he claims is four times as potent as ordinary serum.

Sir Almroth Wright published in the *Lancet* of August 1st, 1932, his views on the action of different antiseptics in the treatment of septicaemias. He is unconvinced of the bactericidal properties of corrosive sublimate, sanocrysin, mercurochrome, trypaflavine, or gentian violet when injected intravenously. Novarsenobenzol, he admits, has an antiseptic property against certain germs, particularly the haemolytic streptococcus and anthrax bacillus. Yet, despite Wright's criticisms, the drugs he condemns as useless enjoy considerable popularity, if not always success. On the other hand, a case of death from acute oedema of the lung following a fourth injection of 5 c.cm. of trypaflavine in a 2 per cent. solution is reported by Chauvin. The use of gold salts in the treatment of phthisis seems to be increasing, and several authors take considerable pains to insist upon the need for caution in their employment. Grave anaemias, purpura, and multiple haemorrhages are attributed to " aurotherapy." Intravenous injection of alcohol (66 c.cm. of absolute alcohol in 140 c.cm. of physiological serum) has been employed with success in cases of puerperal sepsis, as well as in pneumonia, abscess of the lung, and streptococcal endocarditis. Among the diuretics recommended Glaessner advocates the oral administration of distilled water for uraemia, hypertension without arteriosclerosis, and urinary lithiasis ; Vallery-Radot and Gilbrin have used with success in cardiac dropsy ammonium nitrate, 8 to 12 grams daily for several days with or without a mercurial diuretic ; ammonium chloride or bromide has been found to increase the diuretic action of novasurol, and Nonnenbruch has practised successfully intra-abdominal injection of salyrgan (2 c.cm.) in cases of ascites. Various new remedies and measures have been introduced for dealing with arterial hypertension, such as subcutaneous injection of sodium cholate, 0.05 to 0.1 gram in strictly isotonic solution, and of potassium rhodanate, 0.3 gram thrice daily by mouth, but the latter drug has dangerous toxic properties. Hypertonic glucose solution injected intravenously is recommended by Roch and others ; while surgical measures, consisting of division of the left splanchnic nerve, may produce a long-lasting fall in pressure. Angina pectoris has been ameliorated by intravenous injections of *iodine* and iodides and by subcutaneous injections of CO_2: the methods may be used either alternately or simultaneously. Operative measures as practised by Leriche and Fontaine have yielded such remarkable results in

seventy-eight cases of recurrent angina as to deserve the closest attention.

Liver therapy in pernicious and other grave anaemias continues to prove its value, and intravenous injection of liver extracts is efficacious in many cases in which oral administration has failed. The advances made in anaesthetics with intravenous injections of such drugs as pernocton, nembutal, and sodium bromide are noteworthy. The importance of ephedrine to counteract the collapse which occasionally follows spinal anaesthesia is amply borne out. New methods for relief of pain are always welcome. In this group it is recorded that migraine and tabetic pains have yielded to injections of antirabic virus vaccine ; intravenous injection of atropine gives relief in tabetic pains and especially in gastric crises ; and for strains and traumatic arthritis Leriche and Fontaine practise daily injections into the periarticular tissues of 20 to 25 c.cm. of a 1 per cent. solution of novocain without adrenaline. Radiotherapy and surgical intervention in syringomyelia, according to Schaeffer, may to a large extent arrest the progress of this disease. The treatment of Addison's disease with extract of suprarenal cortex has yielded in a few instances brilliant results, but the expense of the preparation prevents, in some cases at least, the adequate administration of this seemingly potent remedy. An interesting addition has been made to the treatment of gastric ulcer and hyperchlorhydria with the injection of extract of the posterior lobe of the pituitary. This decreases the gastric acidity by increasing the excretion of the urinary chlorides, thereby diminishing the chloride content of the blood. The treatment of non-tuberculous pulmonary suppuration formed an important topic of discussion at the fourth Congress of the International Society of Surgery held in Madrid in March, 1932. Evidently operations on the lung are at last taking their rightful place in the domain of surgery, although it is long enough since Macewen of Glasgow demonstrated their practicability. Bronchoscopy, too, offers another valuable mode of approach to, and drainage of, abscess of the lung.

THE OUT-PATIENT PROBLEM

Exactly a year ago a committee of the King Edward's Hospital Fund for London was appointed to inquire into out-patient methods at London voluntary hospitals as affecting the suitability of patients and their time of waiting. The report of that committee is issued this week, and a brief summary will be found at page 31. The inquiry has evidently been painstaking and extensive, and the report is carefully drawn up. It contains a great deal of material which will have to be very fully considered by the boards of management of the voluntary hospitals in the area to which it relates, and there is much in it of importance to all private medical practitioners, as well as to the medical and surgical staffs of those hospitals. One section of the report will be of special interest to those who are connected with district nursing services. No doubt, also, the Council of the British Medical Association will consider the whole document in due course through the appropriate machinery. Pending this more detailed scrutiny by various bodies or persons, certain facts and impressions may be noted as affecting general practitioners in the area of King Edward's Fund and their relation with the out-patient departments of hospitals within that area. It is significant that the total number of out-patients, which dropped heavily after the coming into operation of the national health insurance scheme, though rising in recent years, has (contrary to what is believed to be the case outside the metropolitan area) not yet reached its former level by a considerable margin ; but that, on the other hand, the number of out-patient *attendances* has much increased. In this respect Guy's Hospital and the London Hospital present a contrast: the former, in 1931, had 122,867 new out-patients with 554,606 attendances ; the latter (which is understood to apply certain restrictions, especially with regard to insured persons) had, as corresponding figures, 81,389 and 492,645.

The main points to which the committee applied itself were overcrowding and waiting. It is clear, though the evidence may be difficult to formulate, that both are prevalent. A number of relatively small reforms which are suggested or may be devised would, cumulatively, reduce the times of waiting ; but overcrowding can, apart from structural changes, be dealt with only by a consideration of the suitability of patients and a careful choice of those to receive attention as out-patients. This is the point in which the practising medical profession is chiefly interested, and it will be remembered that evidence was given before the committee on behalf of the British Medical Association in accordance with the decisions of the Representative Body in 1931 as set out in the Association's pamphlet, *The Problem of the Out-Patient*. The committee reached conclusions which appear to be unnecessarily timid. As set out categorically towards the end of the report the actual recommendations are not unsatisfactory so far as they go. Their tendency is even more definite than the discussion in the body of the report would have led one to expect ; but it is difficult to avoid the impression that the committee, as a whole, favoured the obsolescent " open door for the sick poor " idea, and was disinclined to realize the revolution that has been made by the public provision of a number of alternative methods of obtaining medical attention. Of course, the committee discusses these methods, and recognizes the need for even further filtration, but it is curiously unwilling to admit the validity of any selective agency outside the staff of the hospital itself, and evidently feels suspicious of the best of such outside agencies—namely, the general practitioner himself. We are sure, however, that there are certain members of the committee (not all medical) to whom these remarks do not apply, and who individually have a greater confidence in the profession.

In its pronouncement the British Medical Association says: " The types of cases for which the out-patient department should properly be utilized fall into three

groups: (1) casualty cases; (2) consultation cases, including those retained for special treatment; (3) discharged in-patients." The committee commends the adoption of this principle in London County Council hospitals, and recommends that voluntary hospitals should be "encouraged to develop" their out-patient work on these lines. We wonder why the committee hesitated to adopt the recommendation of the Association that "only such treatment should be given at the out-patient department as cannot in the best interests of the patient be obtained elsewhere under the usual arrangements as between private practitioner and private patient, or under contract arrangements." If there is nothing to be said against so simple and useful a statement, why not endorse it? The committee's attitude is a little clearer towards the further recommendation of the Association, that "no person, except in cases of emergency, should be accepted for treatment as an out-patient at a voluntary hospital unless he brings a recommendation from a private medical practitioner, a provident or other dispensary, a public clinic, or from a public assistance medical officer of a local authority." The committee is inclined to think that the public assistance case should go to the county hospital, and that it is well to encourage the recommendation from a practitioner and intercommunication between him and the hospital staff. But it objects to establishing this as a rule—first, because in teaching hospitals this might lead to a scarcity of suitable clinical material; secondly, because there are some people for whom there is no alternative provision without fee; and, thirdly, because there are cases in which it is a good thing for a patient to seek further advice without the knowledge of his own doctor, even though easy means are available for changing the doctor should the necessary certificate or report be unreasonably withheld. The committee makes no attempt to justify this last opinion: it merely says that "there are strong arguments" in its favour. Due weight must be attached to the other two; but reasons are given in the B.M.A. pamphlet for regarding them as of very limited validity and extent.

On the whole, considering how far the committee has gone in its definite recommendations in the direction of the Association's policy, and remembering that that policy was adopted not for immediate and universal application, but for its educative value and with a view to its gradually being put into practice, there is no reason to be seriously dissatisfied with the report. Finally, we should like to draw attention to a thoughtful paragraph in which the case for co-operation between the hospital and the general practitioner and for the development of the consultative side of the out-patient department is admirably put. "The general practitioners would benefit by being brought into more frequent touch with the visiting staff and with the latest improvements in medical science. The visiting staff would not approach the patient as if the occasional visits to hospital were the only kind of medical attention he received, and as if his dossier in the hospital registry contained the whole of his medical history, but would take into account the family doctor as part of the environment affecting his past, present, and future condition. The medical students would realize more clearly the relation between the science of medicine and its application to everyday life, and, when qualified, would regard the hospital, not as a place of education which they had left behind, but as an important part of the available facilities for the efficient conduct of their practice."

MEDICAL HONOURS

The outstanding feature of the medical New Year Honours, of which a full list appears in another column, is the barony conferred on Sir Thomas Horder, Bt., Physician-in-Ordinary to the Prince of Wales, and senior physician to St. Bartholomew's Hospital. Sir Thomas Horder has long been known to his students and colleagues as a general clinician of extraordinary merit in a time of intensive specialization. As teacher, lecturer, and consulting physician his name is familiar to the whole profession, and, notwithstanding the heavy claims of hospital and private practice, he has found time to give service in medico-sociological causes. We welcome his elevation to the peerage. In debates in the House of Lords on matters touching science and the health of the people his keen intellect and command of lucid phrase should be valuable in interpreting medicine and the medical point of view to an assembly always attentive to the expert on his own ground. Social legislation pays too little heed to the teachings of biology. There is so much political incapacity and general muddleheadedness in public life to-day that a fully instructed member with the gift of orderly exposition can make his presence felt in Parliament when national policy is on the anvil. We hope that Sir Thomas Horder—like Lord Dawson and Lord Moynihan, whom he now joins—will not hesitate to "bring down the knobkerry" when this is needed in the House of Lords.

Among the other honours announced on Monday we may particularly note the K.C.I.E. conferred on Major-General John W. D. Megaw, who has served with distinction as Director-General of the Indian Medical Service during the past three years and was previously well known as pathologist and expert in tropical medicine, and as editor of the *Indian Medical Gazette*. Dr. Frederic J. Willans, Surgeon Apothecary to the King's Household at Sandringham, is created K.C.V.O.; and knighthoods are conferred on Dr. John L. McKelvey of Sydney for his services to surgery in the Commonwealth of Australia, and on Dr. San Crombie Po, formerly municipal commissioner at Bassein and member of the Burma Legislative Council. We mention also, because of his services to comparative medicine, the knighthood conferred on Professor Frederick Hobday, principal and dean of the Royal Veterinary College and editor of the *Veterinary Journal*; and, because prelates are very rare in our profession, the Kaisar-i-Hind medal for public services in India awarded to Dr. Kennedy, Bishop of Chota Nagpur.

FIG. 1.—Osteo-arthritis of the right hip in an elderly patient showing flattening of the head, loss of joint space, and displacement outwards. The os acetabuli is seen on both sides.

FIG. 2.—Osteo-arthritis of the right hip in a case of bilateral coxa vara of the adolescent type.

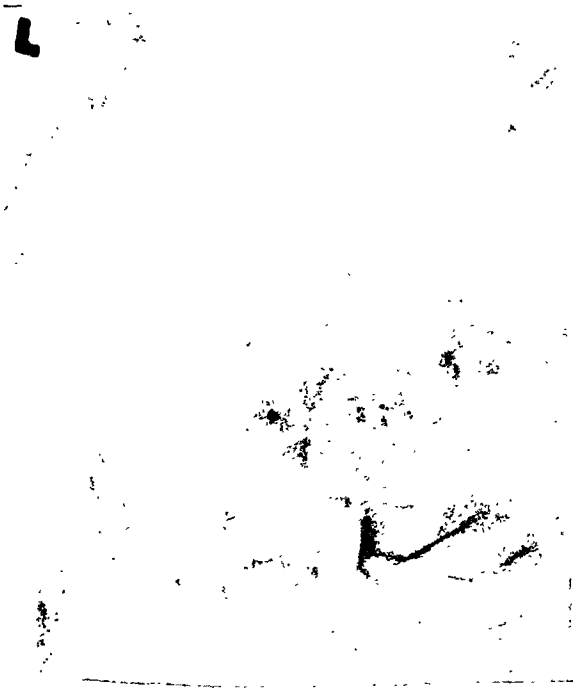

FIG. 3.—Osteo-arthritis in a case of subluxation of the hip probably of congenital origin. The way in which the pressure is carried by a limited portion of the top of the head is well seen.

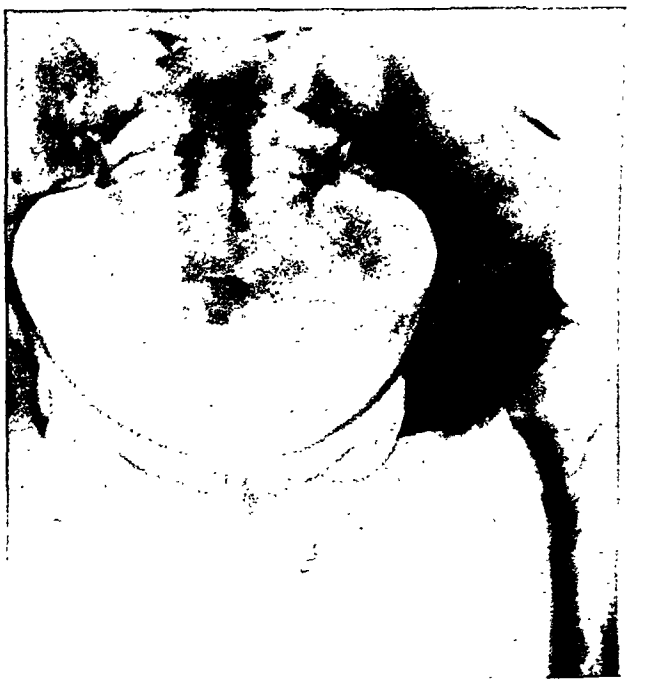

FIG. 4.—Osteo-arthritis of the hip in a case of syphilis. There is a patchy rarefaction of the head of the femur, loss of joint space, and osteophytic formation.

THE INDIAN ROUND TABLE

onfusion between the British Medical Association ıe General Medical Council is so inveterate that :spairs of ever clearing it up so far as the lay press ; country is concerned, but it was certainly rather sing to find the same confusion persisting in the ı Round Table Conference at the House of Lords. s evident that some speakers, both British and a, were talking of the British Medical Association the General Medical Council was what they had nd. One British delegate said he desired to put record that in his opinion the British Medical Asso- n had not been altogether wise in its handling of ndian question, and another holding a still more rtant official position declared that Indians could on him not to take the side of the British Medical ciation against India. The question of the conflict een the General Medical Council and the Indian ersities was raised by a prominent Indian, who took ı remark in one of the committee reports that ing agreement between a Medical Council in India the General Medical Council some special provision ıt be required regarding the right of practitioners tered in the United Kingdom to practise in India. ill is shortly to come before the Indian Legislative ıcil for the constitution of an Indian Medical ncil, and it is anticipated that it will lay down certain guards for medical education and regulate medical ees in such a way that the constant disputes which : arisen with the General Medical Council in this ıtry will be obviated. The demand of the Indians, ıut forward by this speaker, was that if medical cation was to be standardized, this should be done ıugh the Indian Medical Council, and he wanted to w what would happen supposing agreement between ı a council and the General Medical Council were reached. He thought it must be left to the good se of the two bodies, the one in India and the other England, to regulate the rights of practitioners on a is of reciprocity. On the British side, from more n one quarter, it was pointed out that nothing must done legislatively which would give countenance to suggestion that it was open to the Government of lia so to discriminate against British doctors that ıe would be available to deal with persons of British th in India. The Indian delegate who had spoken ılied that he fully realized that Indian graduates must ne to British universities for higher medical educa- n, and he disclaimed any desire on the part of India penalize the British practitioner ; all that India sired in this matter was power to negotiate on a basis reciprocity. Another Indian delegate expressed a ong view that the two bodies, in England and in dia, should come to terms before the new Act reached e Statute Book. He added that this medical question ıd reached considerable dimensions in India, and was coming a first-rate political issue. The speeches on ıe British side were persuasive, begging the Indians appreciate the British point of view even as their wn was appreciated, and not to suggest that because ıdia had failed to arrive at agreement with the General ledical Council, even though the fault might be with ıat body, therefore British residents or travellers in ndia were to be penalized and not allowed to have ritish doctors. The short debate concluded with a promise on behalf of the India Office that it would do its best to secure a reasonable agreement before any new Act came into force.

MASSIVE RADIUM UNITS

In the early part of last year a decision by the Radium Commission to discontinue the use of a massive radium unit (the 4-gram radium bomb) aroused much discussion, culminating in a correspondence in the public press. In view of the importance of the questions at issue the Presidents of the Royal Colleges of Physicians and Surgeons summoned a conference representing the leading learned societies of the medical profession. The conference met on March 4th, when it immediately appeared that the matter was of a highly technical nature, upon which full information must be obtained before any conclusion could be reached. The conference therefore appointed a technical committee of experts to obtain the necessary information and to report to it. This committee, having considered in the most thorough manner the questions referred to it, and having obtained information from the leading radium centres both in England and abroad, has now presented its report, which we print in full at page 28 of our present issue. This report takes the form of a reasoned statement, leading to the unanimous conclusion that a massive unit should be established in this country containing not less than 5 grams of radium element. The arguments supporting this conclusion are founded upon a close analysis of the problem from its theoretical aspects, upon the experience of members of the committee in the clinical use of radium, upon the results they have seen in the chief radium centres both at home and abroad, and upon the views of all who have had charge of large radium units. The committee's conclusions gain reinforcement from such cautious and experienced observers as Professor Regaud of Paris and Professor Forssell of Stockholm, whose clinics were visited on its behalf by Mr. Souttar and Professor M'Lennan. It appears that at every centre where a large unit is in use arrangements have been made to increase it, and that an international committee has recently decided to establish a unit at Brussels containing as much as 15 grams of radium element. Provision of the unit is, however, but a small part of the work which must be put in hand if full advantage is to be taken of the opportunity its possession would offer. It must be so placed that the patients can be drawn from the widest possible area, it must be in charge of experts who are prepared to regard it as their first interest, and these experts must have freedom alike in the choice of their cases and in the method of treatment they adopt. Associated with the unit and under the same control there must be an organization fully equipped for modern operative surgery, for deep *x*-ray therapy of the most advanced type, and for physical, pathological, and biological researches on the highest plane. The advances in radium therapy which are to-day being made in Paris and Stockholm would have been impossible without the complete organizations that have been built up in those centres. The problems involved are so complex that they can never be encompassed by any one worker ; they will tax all the abilities of the surgeon, the pathologist, and the physicist ; and even then (as has often been urged in these columns) the closest co-operation is an essential condition of their solution.

INFLUENZA

Influenza is paying us another visit. During the last two or three weeks it has appeared in various parts of the country. Birmingham seems to be suffering most. Portsmouth, Glasgow, Southampton, and Durham, among other towns, have had their various activities to some extent interfered with by the epidemic. London was one of the last places to be attacked. Medical practitioners are perhaps only too familiar with this will-o'-the-wisp of medicine. The diagnosis of influenza may be often made more by faith than by knowledge, but the disease, unfortunately, does exist. Most of our readers probably have their own schemes of treatment, but those who have not, and also those who have, will find helpful advice in Dr. H. Morley Fletcher's article in this month's *Practitioner*. He recommends mixed vaccines and vitamin A as prophylactic measures. For treatment he insists upon the need for absolute rest in bed in a well-ventilated room. Immediate purgation with calomel; Dover's powder (to 10 grains) with a hot drink at night to relieve cough and restlessness; a milk diet, including a liberal supply of fluids; a mixture containing quinine sulphate (1 grain), sodium salicylate (10 grains), and 20 to 30 grains of potassium citrate to be given four-hourly; an appropriate gargle; phenacetin and aspirin for headache; 7½ grains of medinal for insomnia; menthol and tinct. benzoini co. for inhalation—these and other therapeutic details are given. In an admirable epitome of the treatment of pneumonia Dr. Morley Fletcher mentions an old remedy now much neglected: "If cyanosis be present, dry cupping, followed by poulticing, should be performed over the back." For increasing cyanosis venesection is indicated. The early administration of oxygen by the continuous nasal method is recommended at the onset of bronchopneumonia. If there is any suggestion of heart failure tincture of digitalis (7½ minims four-hourly) should be given; and, in urgent heart failure, 1/250 of a grain of strophanthin should be injected intravenously and repeated four-hourly if necessary. Attention is drawn to the need for care during convalescence. The management of gastro-intestinal and of institutional influenza is dealt with in the same number of the *Practitioner* by Dr. A. H. Douthwaite and Dr. G. E. Friend respectively. The *Memorandum on Influenza*, published by the Ministry of Health in 1927 and reprinted in 1929 (H.M. Stationery Office, price 2d. net), also contains useful information.

EPIDEMIOLOGY OF WHOOPING-COUGH

It is remarkable how little attention relatively has been paid in the past to whooping-cough in view of the facts of its high incidence (about 40,000 cases each year in London, for example), the serious impairment of physique which so often ensues after an attack, and the varying but often high mortality. Permanent damage of the respiratory, circulatory, and nervous systems is an all too common sequel. With the aid of a scientific grant awarded to him by the British Medical Association in 1930 and 1931, Dr. Percy Stocks, reader in medical statistics in the University of London, assisted by Miss Mary N. Karn, has performed a useful service in undertaking a comprehensive survey of the extent and ravages of this disease, special attention having been paid to the boroughs of Battersea and Greenwich. The conclusions reached in this investigation have been published in the November issue of the *Journal of Hygiene*, and establish the fact that this must now be considered, in London at any rate, the most important epidemic disease of childhood as regards the infliction of physical and nervous suffering, loss of school attendance, the subsequent impairment of health and resistance to other maladies, and the considerable death rate. In the two boroughs mentioned it was found that epidemics of whooping-cough tended to have a biennial periodicity, a summer outbreak being often followed by, or merging into, a winter outbreak, which had subsided by the ensuing midsummer. There then followed a year of low incidence. The general picture presented was thus an alternation of epidemic and interepidemic years. Such epidemics did not always run concurrently in parts of London separated by several miles; the spread was checked to some extent by barriers to free communication, and small districts occasionally escaped, or an interval of several months might separate the epidemic peaks in districts a mile or so apart. The usual view that the epidemic cycle in whooping-cough could be explained by a periodic reduction of the proportion of children not previously attacked below some critical limit was negatived by the investigation, and Dr. Stocks believes that both the dying down of epidemics and their periodicity can be explained by the occurrence of a latent immunization of contacts, as in measles, such immunity lasting only about one year instead of two or three. He bases this conclusion on: (1) measurement of the rise and fall of apparent infectiousness of cases to other children in the same house during six years in Battersea; (2) measurement of the frequency of second cases in houses after different intervals of time during a decade in Greenwich; and (3) an analysis of the attack rates among home contacts in Holborn and Battersea during several years following exposure to infection, as compared with those among control groups of children. These phenomena would be difficult to explain as resulting from a "cycle of activity" of the organism. Using the figures obtained in these boroughs as a basis, the conclusion is drawn that about 60 per cent. of London children have had whooping-cough by the tenth year of life, and about 61 per cent. at some time during life, this proportion being rather lower than estimates made from histories given by parents in a group of American towns. The escape from infection of the remaining children must be by virtue of the acquirement of some kind of immunity, or its inherent possession. Superimposed upon the gradual rise and fall of infectiousness believed to be due to these immunity changes, there occurs a sudden rise at the commencement of an epidemic, which must be attributed to an enhanced real infectiousness. Dr. Stocks remarks that this probably arises from a sudden increase in activity of the organism itself under seasonal influences setting in at the moment when the herd immunity becomes insufficient to withstand the infection pressure; the balance is consequently upset and the epidemic begins. He adds that these findings are similar to those for measles, the chief difference being that: (1) epidemics of whooping-cough are usually spread over a year, instead of six months in the case of measles; (2) latent immunity apparently lasts about a year, instead of two or three; (3) about 60 per cent

hildren are attacked at some time during life, ıd of about 90 per cent. ; (4) there is probably eat immunity for whooping-cough in a certain ortion of children, but not for measles ; and (5) the of latent to manifest infections is lower.

: WILLIAM HALE-WHITE AND THE GUY'S HOSPITAL REPORTS

ıuble number of the *Guy's Hospital Reports*,[1] con- ng thirty articles, the first eleven of which are by er house-physicians of Sir William Hale-White, is ated to him in celebration of his seventy-fifth birth-

Sir William was editor of the *Reports* for seven rs, and the two earliest of his thirty-seven contribu- s to them were made half a century ago. So this ıuies a jubilee. He has recently rendered another ice by analysing the articles in the *Reports* during eriod almost corresponding to his contributorship. articles cover a wide field, and, indeed, seem to ord the evolution of his career, for in 1882 he jointly orted abnormalities observed in the dissecting room ng 1880–2 ; this was followed by papers on rbid anatomy and on clinical medicine, and more ently by historical studies of Wilks, Bright, Hodgkin, dison, and other Guy's men. Among the articles by former house-physicians there are three from distant ts of the world—India, Australia, and New Zealand hus pointing to his widespread influence, and to the obtrusive activity of the editor who has organized splendid tribute of affection. Dr. H. C. Cameron ıes fully on the condition described by Eliasberg and land as epituberculosis, in which children with idence of tuberculous infection elsewhere show signs extensive consolidation of a lung but recover, thus ggesting an infiltration of the lung, which, though not berculous, is around an area of tuberculous activity. other of Sir William Hale-White's former residents— . E. P. Poulton—takes up the subject of urea tests kidney function. Dr. T. B. Heaton describes experi- nts made in the pharmacological laboratory at xford which suggest that many ordinary foods contain growth-inhibiting factor. For this factor, which is ntagonized by the vitamin fraction B_2, the name itamin I is suggested. In recent volumes of these *eports* there have been symposia on streptococcal nd staphylococcal infections, and this instalment con- ins one on *Bacillus coli* infections. By a happy hought the first article is one by Sir William, published n 1912, on the importance of examining the urine acteriologically, and dealing largely with this infection. Dr. Ryle treats the subject generally, and other articles ollow, the editor contributing the seventh and last, on *P. coli* cholecystitis. There are also three articles on ncreatic disease, a subject Sir William thoroughly xplored in 1897, and several papers by Dr. L. J. Witts nd others on acute diseases of the blood-forming rgans. This double number is a deserved and pleasing tribute to a great clinical physician of the Guy's school.

[1] *Guy's Hospital Reports*, vol. 82 (vol. 12, fourth series), Nos. 3 and 4, October, 1932. Double number, dedicated to Sir William Hale-White, K.B.E., M.D., F.R.C.P., in celebration of the seventy-fifth anniversary of his birthday. Edited by Arthur F. Hurst, M.D. London: Guy's Hospital; and Headley Brothers. 1932. (Pp. 257-508 ; illustrated. Annual subscription for four numbers, £2 2s. ; this number, 22s. 6d.)

MISS LAWRENCE

Miss A. L. Lawrence has been chosen to succeed Miss Eleanor Christopher, M.A. (who retires at Easter), as Principal of St. Hild's College, Durham, the diocesan training college for women and a hall of residence of the University of Durham. Miss Lawrence was appointed Intelligence Officer by the Council of the British Medical Association in 1919, after serving for two and a half years on the staff of the Central Medical War Committee, for which she was awarded the M.B.E. She had entered Girton College, Cambridge, as a Cloth-workers' Scholar in 1910, and gained honours in Part I of the Historical Tripos and first-class honours in Part II. In 1925 she attained the standard for honours in Part II of the Law Tripos. On the strength of these academic distinctions she was admitted to the titles of M.A. and LL.B. Cantab. Miss Lawrence's work for the British Medical Association during the past fourteen years has been done behind the scenes, and its extent and value are known to comparatively few outside the circle of officers, committeemen, and officials. Those whose duties bring them into touch with headquarters appreciate very highly the zeal and ability and devotion with which she has served the Association, and her readiness to assist in any good cause. A striking example of her constructive and analytical gifts was the report on the work and problems of the Colonial Medical Services, published anonymously in our *Supplement* of July 4th, 1931. On behalf of every worker for the Association—and in a special degree on behalf of the *Journal*, which owes much to her self-effacing help in matters large and small—we wish all success to Miss Lawrence in her new field of endeavour and say good-bye regretfully to a loyal colleague.

The annual meeting of the British Association in 1933 will be held at Leicester from September 6th to 13th, under the presidency of Sir F. Gowland Hopkins, P.R.S. ; there will be thirteen sections. Professor E. D. Adrian, F.R.S., will be president of the Section of Physiology.

We regret to announce the death, at Dundee, in his eightieth year, of Dr. Alexander Mitchell Stalker, emeritus professor of medicine in the University of St. Andrews, and for many years physician to the Dundee Royal Infirmary.

The next annual congress of the Royal Institute of Public Health will be held at Eastbourne from Tuesday, May 30th, to Sunday, June 4th, 1933 (Whitsuntide), under the presidency of Viscount Leverhulme. The scientific work of the congress will be conducted in the following Sections: (1) State medicine and industrial hygiene ; (2) women and children and the public health ; (3) tuberculosis ; (4) pathology, bacteriology, biochemistry, and veterinary medicine ; (5) climatology and hydrology. Delegates are being invited from the Governments, the municipalities, the universities, and other public bodies of Great Britain and Ireland and the British Dominions, as well as from Continental and foreign countries. Arrangements have been made with the railway companies for a reduction in the fares. The headquarters of the institute are now at 23, Queen Square, W.C.1.

REPORT OF RADIUM CONFERENCE

We have received for publication the following report of the conference on massive radiation (radium "bomb") summoned by the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England, which met on March 4th, (See *British Medical Journal*, May 21st, 1932, p. 952), *November 24th, and December 19th, 1932. This report is followed by that of the technical committee of experts appointed by the Conference.*

The Conference owes its origin to doubts publicly expressed as to the soundness of the decision of the Radium Commission to withdraw the 4-gram bomb, then in use for massive radiation at the Westminster Hospital, and subdivide it into four units of one gram each.

It consisted of the following members:

Lord Dawson of Penn	President of the Royal College of Physicians (In the Chair)
*Lord Moynihan	President of the Royal College of Surgeons
Mr. Wilfred Trotter	Medical Research Council
Sir Frederick Menzies	Chief Medical Officer, London County Council
Dr. Watts Eden	President of the Royal Society of Medicine
Mr. H. S. Souttar	British Medical Association
Professor Arthur Hall Mr. Ernest Miles Professor Woodburn Morison	Radium Commission

In the interim report, dated March 4th, 1932, the Conference decided unanimously "that the Radium Commission arrived at a sound conclusion in discontinuing the use of the 4-gram bomb at the present juncture, though this decision is without prejudice to the question of the therapeutic value of 4-gram or even larger aggregations of radium," and "that in the opinion of this Conference a fully equipped radium institute is needed in London, where the more difficult and speculative problems connected with radium and ray therapy can be studied by the combined efforts of a trained staff."

The Conference decided to appoint an expert committee; the constitution of this committee was as follows:

Lord Dawson of Penn, P.R.C.P.
Lord Moynihan, P.R.C.S.

Chairman:
Mr. H. S. Souttar

Physics:
Lord Rayleigh, F.R.S.
Professor J. C. M'Lennan, F.R.S.

Radiotherapy and Medicine:
Dr. Roy Ward (Radium Institute)
Dr. G. F. Stebbing (Lambeth Hospital, L.C.C.)
Dr. B. W. Windeyer (Middlesex Hospital)

Surgery:
Mr. Cecil Rowntree (Cancer Hospital)
Mr. Geoffrey Keynes (St. Bartholomew's Hospital)

Gynaecology:
Mr. Louis Rivett (Middlesex Hospital)
Dr. Elizabeth Hurdon (Marie Curie Hospital)

Experimental Radiation:
Dr. W. Cramer (Imperial Cancer Research Laboratory).

The reference was "(*a*) What is the scientific case for mass radiation by radium, and what are the advantages and dangers attaching to the use of such radiation? (*b*) What are the advantages and risks of massive surface radiation by radium compared with those of radium needles and radon seeds?"

The Committee reported in the first instance to the Conference on November 24th, 1932, and finally on December 19th, 1932.

* Sir Holburt Waring has now succeeded Lord Moynihan.

The Conference expresses its appreciation and thanks for the signal service which the Technical Committee, under the chairmanship of Mr. Souttar, has performed.

It is clear that there is a field of usefulness for radiation from massive units of radium, given an adequate equipment and men and means. We adopt the view of our committee that it is desirable a radium unit containing not less than 5 grams of radium element should be established.*

An institute specially constructed for the purposes of such radiotherapy and within easy reach of the future Post-graduate School and Hospital is an ideal to be aimed at, but for the moment it may be impracticable upon financial grounds. It would, however, be feasible to organize existing institutions for the time being, provided they were near enough to each other for efficient co-operation. The amount of radium required for a large unit might mean that the allotment of radium by the Radium Commission would need to be further concentrated.

Both *x*-ray and radium therapy are at present advancing so rapidly that it is impossible to decide the position which each will occupy in the future. The whole field is one for the fullest investigation, and it is one in which results of the first importance have already been obtained.

In drawing up this report the Conference has purposely refrained from considering the relative places occupied by surgery and radiotherapy in the treatment of malignant disease.

Signed on behalf of the Conference,

January, 1933. DAWSON OF PENN.

REPORT OF THE RADIUM TECHNICAL COMMITTEE

We beg to report to the Conference as follows:

The Committee held its first meeting at the Royal College of Physicians on June 15th, 1932. Eight meetings in all have been held, and, in addition, various special visits of inspection have been made, including one to the Westminster Hospital Annexe.

Our report is based upon our personal experience in the various branches of radiotherapy to which we have individually devoted special attention, and also upon personal observations upon various visits to the radium centres in London, Manchester, Birmingham, Paris, Brussels, Stockholm, and New York. The Committee has also had the advantage of hearing evidence from Professor Sydney Russ, Mr. Rock Carling, and Mr. Stanford Cade, and was privileged to see a confidential report from Mr. Comyns Berkeley, who has recently visited most of the European radium centres on behalf of the League of Nations. Further, with a view to obtaining the latest possible information as to the progress of treatment by massive units, Professor M'Lennan and Mr. Souttar specially visited the Radium Institutes of Paris and Stockholm.

The report itself deals with the general question of the value of radiation by massive units, and attempts to answer, so far as is at present possible, the questions put forward by the Conference.

Attached to the report is an Appendix giving a detailed account of the most recent work in Paris and Stockholm, in which are set out the views of the leading authorities at these centres.

We would express our thanks to all those who have so generously placed information at our disposal. We would especially mention Professor Regaud of Paris and Professor Forssell of Stockholm, and in this country Mr. Comyns Berkeley, Mr. Rock Carling, Mr. Stanford Cade, and Professor Russ.

H. S. SOUTTAR,
Chairman.

* It is worthy of note that a 15-gram unit is likely to be established in Brussels on the advice of an International Committee.

ALUE OF RADIATION BY MASSIVE UNITS (TELE-RADIUM)

What is the scientific case for mass radiation by ım, and what are the advantages and dangers attach- o the use of such radiation?

What are the advantages and risks of massive .ce radiation by radium compared with those of ım needles and radon seeds?

'elective Action of Radiation upon Malignant Cells

ıe use of radium in the treatment of malignant ɔurs depends upon the empirical observation that large number of instances the cells of malignant ours are destroyed by an amount of radiation insuffi- t to destroy the normal tissue. This proposition is rally true over a very large range of wave-lengths, certainly holds over a range which extends from ys with a wave-length of 1 A.U. to hard gamma rays ı a wave-length of 0.04 A.U. or less. In spite of an ıense amount of research devoted to this particular ıt, it is still uncertain whether there is any specific erence between the longer and shorter waves in their ct upon the cells, although there is a general im- ssion that radiation of short wave-length has a higher rse of selective action upon the cells of malignant ıours in virtue of their rapid growth.

Penetrating Power of Short Waves

What is, however, quite certain is the physical fact t radiation of short wave-length has a higher pene- ting power, and is therefore capable of conveying rgy into the deeper tissues, whilst radiation of longer ve-length is absorbed in the more superficial tissues, l there expends a large part of its energy. It is this reason that *x*-ray apparatus is being made generate *x* rays of shorter and shorter wave-length, t no apparatus has yet been devised to generate waves short as the harder gamma rays of radium. These ort-wave generators are still on trial, and it is of im- rtance that we should be able to compare the results tained from them with those obtainable from mass diation by radium.

Importance of Uniform Field

The margin between general destruction of the tissues ıd selective destruction of the malignant cells which are vading them is very small, and it is therefore an essential ctor in treatment that every element of tissue through- ıt the region treated should receive exactly the same ount of radiation, for if at any point there is a defect ɔme malignant cells will survive, whilst if at any point ıere is an excess, the supporting tissues will be destroyed. In the treatment of malignant tumours by radio- ıerapy, whether by means of *x* rays or of radium, there indeed a general agreement upon the importance of btaining a uniform field of radiation throughout the egion under treatment. Whatever method has been dopted, its clinical success has always been proportional o the accuracy with which this physical problem has ɔeen solved, and there are strong grounds for believing hat upon its more complete solution may depend the vhole future of radium therapy in the treatment of ancer.

Physical Problem of the Uniform Field

So far, therefore, as our present knowledge is con- cerned, the solution of the exceedingly complicated clinical problem of the treatment of malignant tumours by radiation would appear to depend primarily upon the solution of the physical problem of obtaining a uniform field of radiation—that is to say, a field throughout which the scalar value of the energy absorbed is constant, both in the cross section and in the depth of the field.

The Advantage of Gamma Rays

For this purpose gamma rays present a very definite advantage over *x* rays, since, owing to their shorter wave- length, they have a proportionately greater penetration. Although in both instances the intensity of the field diminishes with the distance from the source, it is far less affected in the case of gamma rays by the absorption of the tissues, and it is therefore easier to maintain a uniform field as the depth below the surface increases.

It is true that the great volume of power available in the modern *x*-ray tube allows of a greater working distance, so that the proportion of energy delivered in the depth of the body by *x* rays may be equal to, or even greater than, that obtained from radium. But the use of such a volume of energy presents a disadvantage, since there is general agreement that *x* rays produce more constitutional disturbance than do gamma rays of equal adequacy, possibly owing to the more complete absorption which *x* rays undergo in the tissues.

The relative value of the two methods can only be discovered by further experience.

Massive Radium Units at a Distance (Tele-radium)

The use of massive units of radium outside the body furnishes a powerful means of subjecting a region of considerable volume to a uniform radiation by gamma rays, and if a sufficiently large quantity of radium were available this would prove the most perfect physical solution of the problem. It is not, of course, sufficient to use a single beam, since the unavoidable fall in intensity as the distance from the surface increases necessitates a dosage which exposes the proximal tissues, and especially the skin, to an excessive radiation. This, however, may be overcome by the use of multiple ports of entry, and by exact calculation an almost perfectly uniform field can be obtained throughout any volume of tissue where it is required.

Other Methods of Applying Radium

The difficulty of obtaining sufficient radium for use by this direct method has compelled surgeons to devise other methods, by which radium, being brought into closer contact with the tissues, is used to greater economic advantage. The application of radium plaques, the insertion of needles, and the insertion of seeds all come under this heading, and there is no doubt at all that when properly applied in suitable regions they may combine economy with efficiency. They present a further advantage that, owing to the smaller amount of radium used, the effects are strictly localized, and neither the patient nor the attendants are exposed to the possible dangers associated with large quantities of radium.

Defects and Limitations of Interstitial Methods

Although these methods have in many instances given brilliant results, and are probably of permanent value, they present the disadvantage that they do not produce the ideal uniform field of radiation, and in spite of their success, it is still an open question whether massive radiation may not produce even better results when applied to the same situations. This view is certainly supported by the work of Berven on cancer of the buccal cavity, where the results obtained are far superior to those which have hitherto been accomplished either by surface or interstitial methods. The question is one of the greatest importance, but it can only be settled by future work.

The use of needles and of seeds is further limited by the fact that it necessitates surgical access to the region of the tumour, and not merely to the tumour itself but to the whole of the neighbouring lymphatic area through which it may disseminate. This is often undesirable and frequently impossible, and, indeed, there are only a limited number of situations in which it is possible to treat effectively by these means the whole region under suspicion.

Regions Still to be Explored

In spite of the variety of methods now available it is still only in special instances that radiotherapy has been applied to cancer with success, and there remain whole regions where this has not yet been achieved or even seriously attempted ; as examples we may cite deep-seated tumours in the thorax and abdomen. It is here that massive radiation with its penetrating rays appears, at first sight, to offer the solution of the problem, but difficulties arise which are *not merely* physical but are inherent in the disease.

Such tumours are inaccessible to early diagnosis and, in the great majority of cases, are far too advanced when diagnosed for treatment of any kind to be successful. They arise often in tissues which are themselves very radiosensitive, such, for example, as the stomach, the intestine, and the rectum, and the annihilation of the tumour may involve the destruction of the organ from which it has sprung. Moreover, the exact extent of lymphatic involvement cannot be determined, so that it is difficult to ensure the complete irradiation of all malignant cells.

In spite of these difficulties there are definite grounds for hoping that, by some combination of irradiation and surgery, even cancer of the alimentary tract may ultimately be brought under control. In this achievement it is the definite opinion of such cautious observers as Forssell and Regaud that radiation from a distance, either by massive radium units or by *x* rays at a potential not yet obtained, will play an essential part.

The Dangers of Radium

Although there is still very little known about the precise action of gamma rays upon the tissue cells, practical experience is so far advanced that any of the methods which we have mentioned may be employed by experts without danger either to the patients or to themselves. In the hands of the inexperienced the use of radium in any form is dangerous, and an attempt to assess the degree of danger would be more curious than useful.

The insertion of seeds or needles or the application of local plaques in expert hands leads to the disappearance of a tumour with only a moderate local reaction, and, except in the case of a large tumour, with very little constitutional disturbance. A faulty estimation of the dosage or an uneven distribution may lead to gross destruction of the tissues, extensive ulceration of a most painful and intractable type, and even to the death of the patient, whilst there can be no guarantee that the tumour itself has been destroyed. It is true that with a larger mass of radium destruction might be extended to an even wider sphere, but that is the only difference.

All the evidence before us goes to show that the use of massive units of even the largest dimensions can be so completely controlled that the safety of the patient is assured. The occurrence in some instances of severe constitutional disturbance has always been due to some error in technique, and has been avoided on further experience. We are satisfied that there is no foundation for the idea that the use of a massive unit is necessarily associated with any special danger to the patient.

CONCLUSION

The evidence has convinced us that the treatment of cancer by radiation from a massive radium unit (teleradium) is a method the value of which has already been proved, although so far only in a limited field. How far these limits can be extended is a question which can be solved only by co-ordinated clinical, experimental, and physical research in which this country ought to take its share. The larger the unit available the more rapidly will its possibilities be discovered and the wider will be the field which can be explored.

After a full consideration of all the evidence available we are convinced that a large radium unit should be erected in this country, under conditions where such co-ordinated effort is possible, containing not less than 5 grams of radium element.

APPENDIX A

Visit to Paris by Professor M'Lennan and Mr. H. S. Souttar

In view of the importance of obtaining direct information regarding the two bombs at present in use in Paris, an interview was arranged with Professor Regaud at the Institut Curie on July 6th, 1932.

Professor Regaud stated that his experience of the use of 4 grams of radium for distance therapy began in 1924, and had now extended continuously over eight years. Only minor alterations have been made in the construction and mounting of the apparatus, a full description of which will be found in the *Archives de l'Institut du Radium de l'Université de Paris et de la Fondation Curie* (Fasc. II, vol. i, p. 324).

The apparatus consists of a square lead box with walls 6 cm. in thickness, and with an internal area of 150 sq. cm. The radium is contained in eighty platinum tubes with walls 1 mm. in thickness, and is arranged in four groups of twenty tubes each on an internal frame, so that they are situated at the corners of the lead box. The opening of the box is closed up by a block of wax of such dimensions that the plane of the radium is at a distance of 10 cm. from the skin of the patient. As a general rule the treatment extends over seventy hours, and is divided into doses of from two to four hours, according to the tolerance of the patient.

In his whole experience Professor Regaud has never seen any instance of injury to the patient, either local or general, nor has he ever seen any evidence that the treatment has been in any way injurious. It is true that sensitive patients often experience sickness after the treatment, but this soon passes off, and is entirely abolished by reducing the dose on the next occasion.

Carcinoma of the Stomach.—Twenty-five cases of carcinoma of the stomach have been treated after surgical exploration, which had proved that the case was in fact carcinoma and inoperable. In the first group of cases the dose was inadequate (600–900 mc.d.), and no effect of any kind was observed. In later cases the dose was increased to as much as 1,200 mc.d., and definite improvement was noted in several instances. Two of these cases of proved carcinoma are, indeed, alive and free from symptoms after more than four years.

Carcinoma of the Cervix.—One hundred cases of carcinoma of the cervix were treated in two similar groups of fifty each. One group was treated by deep *x* rays working on a potential of about 200kV, the other was treated by radium at a distance. The same local treatment was used in both cases. No difference whatever in the results was noted. Of Class 1 (early cases) the percentage free from symptoms for five years was 83, whilst in Class 3 (advanced cases) the percentage was 34.

Professor Regaud regards treatment by radium at a distance purely as an accessory method and entirely comparable in its effects to deep *x* rays. He quite definitely states that he regards deep *x* rays as the established method and radium at a distance as an interesting and hopeful experiment. He considers it of great importance that far larger amounts of radium should be used. He has arranged for the 4-gram unit at present in use to be increased almost immediately to 8 grams. He has just arranged, in conjunction with Murdoch, Forssell, Holthusen, and Morison, for the provision of a 15-gram unit at Brussels. He is not, however, convinced that developments in *x*-ray apparatus, and the raising of the potential to perhaps a million volts, may not again place *x* rays at an advantage as compared with radium.

Professor Regaud introduced us to Dr. Lacassagne, assistant director, who confirmed fully all that we had just heard. He regarded as of extreme importance in treatment the accurate orientation of the unit, and the limitation of the period of treatment to the tolerance of the patient. He considered it was impossible to treat two patients at the same time satisfactorily from the difficulty involved in their accurate adjustment to the unit. Neither Regaud nor Lacassagne regarded the very wide field exposed in their unit as in any way dangerous; in fact they regarded it as a definite advantage, as it enabled them to treat a larger volume of tissue. They do not connect any special danger with exposure of the liver, the spleen, the kidneys, or the pancreas to radiation, and they stated, in fact, that they had treated with success a case of carcinoma of the liver without any untoward result, the patient being alive four years later. They regarded the skin as one of the most sensitive structures in the body, and the arrangement of their treatment was largely directed to its protection.

Next day, on July 7th, an interview was arranged with Dr. Monod at the hospital, 33, Rue Antoine Chantin, where the 4-gram radium unit is situated. Dr. Monod explained to us in some detail the method of using the unit and of charting the treatment. The unit is being used chiefly for the accessory treatment of carcinoma of the cervix, and in

... the course of treatment extends over twenty-one during which the patient receives the radiation from me.d. The aperture of the unit is 150 sq. cm., and in case the treatment is given with the radium at a ce of 10 cm. from the skin. For the first two weeks riod of treatment is three hours on each day, but in the week this is increased to four hours. The exposures ade through seven distinct portals in rotation, so that portal is not employed again until after the lapse of . Dr. Monod showed us the 4-gram unit and demond the details of its construction. It will very shortly ...eased to 8 grams, but the mounting, screening, etc., t be altered in any way. Dr. Monod confirmed in particular the impression we had gained from Regaud ...assagne. He stated that they had had no serious e, and the results were very satisfactory.

... then went to the suburban anti-cancer centre at uif, 14, Avenue des Ecoles. Professor Roussy was away, ... saw Professor Huginat, his assistant, and Mme Simone rde and Dr. Wickham. Dr. Wickham showed us the m unit designed four years ago by Mme Simone Laborde 1-gram unit, and in continuous use since then. The unit lly described by Gaiffe-Gallot and Pilon, 23, Rue Casimir, Paris, VIIe, in their *Revue* for January, 1929. It is ly to be increased to 5 grams, but without any alteration ... structure. In contrast to the Paris unit, it is provided a series of obturators, so that the beam can be narrowed ... to any convenient size. The radium itself is contained latinum tubes packed side by side in a narrow space, so ... form a focal point of small dimensions. The obturators ... of varying size and shape, with openings ranging from 5 cm. square, and 3 to 5 cm. in diameter. The mini... distance from the skin within which the radium could ...rought was 10 cm.

he unit was used almost entirely as an accessory to local tment, and chiefly in cases of carcinoma of the cervix. ...osures varied with the tolerance of the patient, in most ...nces two exposures a day were given, varying between and four hours each. Dr. Wickham expressed himself as ... satisfied with the results, which he said were very ...ar to those described by Professor Regaud, with whose his own coincided.

APPENDIX B

... on Visit to Stockholm by Professor M'Lennan and Mr. Souttar

...n September 23rd, 1932, we visited the Radiumhemmet in ... holm and met Professor Gösta Forssell, Dr. Ellis Berven, ...ector of the institute, Dr. Rolf Sievert, head of the physical ...oratory, and the staff of the institute.

Dr. Berven demonstrated to us some twenty cases of ...cinoma of the mouth and pharynx in various stages of ...atment by means of the 3-gram radium unit. These varied ...m cases treated five years ago to cases actually under ...tment at the present time. With one exception the tients had not been specially summoned, but were those en in the ordinary course of the "follow through" department. It is the custom at the clinic to group together cases the same character on different mornings, and it happened at this morning was devoted to the mouth and pharynx.

The cases had all been treated by the technique described ... Dr. Berven's book on malignant tumours of the tonsil—... is to say, by primary treatment with the unit, the later ...moval of any remaining growth by endothermy, and the ...al treatment of the region by surface application of radium lement. In the more recent cases the success of the treatent by the unit had been so considerable that no other procedure had been required. It happened that several of the ases of sarcoma and of carcinoma of the tonsil were those escribed in Dr. Berven's article. Among them the following ...y be mentioned in particular:

A woman of 54, treated five years ago for sarcoma of the right onsil. No recurrence, and the only trace of treatment slight carring of the anterior pillar of the fauces.

A man of 62 with carcinoma of the right tonsil invading the ack of the tongue, with large secondary masses in the neck. This ... was treated three years ago by the unit only. No trace of ny growth was discoverable, and beyond extensive scarring and elangiectasis in the neck, and some scarring of the tonsillar ...gion, there was no evidence of previous disease.

A man of 52 with carcinoma in the left floor of the mouth extending far back towards the root of the tongue, with a small secondary gland. There is now no trace whatever of disease.

A man of 65 with an extensive carcinoma actually infiltrating the greater portion of the left lower jaw. Six months ago this man was treated exclusively with the unit. The surface had healed entirely, excepting for a small area of necrosis, where the dead bone had not yet separated.

A man of 80 who came to the clinic six weeks ago with a most extensive carcinoma involving the whole of the right upper lip and extending back within the cheek as far as the tonsil. The case was still under treatment by means of the unit, but all evidence of active growth had disappeared, and the whole area appeared to be healing.

Two cases of very extensive carcinoma of the upper jaw involving the antrum, both in elderly men. These cases had been treated exclusively with the unit. In one of them all trace of growth had disappeared, and he had remained well for some two years. The other was still under treatment, but the recession of the growth was obvious.

A woman of 60 who was treated for a similar growth five years ago was in perfect health. Her case was specially remarkable, as the growth had extended into the nose and backward into the nasopharynx.

Other cases included carcinoma of the tongue, of the floor of the mouth, of the tonsils, and of the pharynx, in many of which secondary glands had been present. The great bulk of the cases were inoperable when first seen, and most of them might have been regarded as surgically impossible, even from the point of view of alleviation. Dr. Berven admitted that they had a certain percentage of failures, but the presentation of such a series of perfect results places beyond any question the value of his method.

The unit was applied in general through an average of six ports of entry, very carefully arranged so as to provide full concentration on the tumour, but to avoid injury to the skin. The success achieved on the latter point was very remarkable, and, with the exception of one or two cases where fixed glands had demanded an excessive local dose, there was no trace whatever of any skin reaction. This was a very remarkable testimony to the value of a narrow beam, and to the very great care exercised in its direction.

THE STOCKHOLM UNIT

Dr. Sievert, who designed the radium unit, demonstrated its construction.

It consists of a heavy mass of lead arranged in the form of the letter L, and pivoted about the middle of the longer limb. The radium itself is contained in a flat carrier, which can be inserted into either of the two slots placed near the extremities of the two limbs of the L.

The box contains sixty tubes of 50 mg. of radium element each, making 3 grams in all, and it is so arranged that these tubes can be concentrated at the centre or brought out to the sides of the box by an external lever.

When inserted in the short end of the unit the radium is brought into its central position. It is protected by the equivalent of 5 mm. of lead, and its distance is 6 cm. from the skin surface. The maximum aperture is a circle of 5 cm. in diameter. At the larger end the skin distance is again 6 cm., with a maximum aperture of 8 cm.

The unit is so mounted and placed as to move with the greatest facility into any position. The smaller end is used for situations where the introduction of the larger end would be anatomically impossible, such as the neck and the perineum. It has, however, a smaller lead protection, the thickness being here only 2.5 cm., as against 6 cm. at the heavy end.

Professor Sievert then showed us his physical laboratory, and the new system of measuring ionization and thereby determining the intensity of the gamma rays with great precision. The essential part of his apparatus consists of two concentric spheres of metal insulated from one another by four points of amber. They can be made of very small size, and he showed us some in which the outer sphere was only 5 mm. in external diameter. The principle consists in charging the inner sphere to a high potential, and then placing the instrument for a known time in a region to be investigated. The inner sphere is discharged by ionization across the intervening air space at a rate proportional to the radiation, and a measurement of the charge remaining on the inner sphere enables the radiation to be determined with great exactness. These instruments have been charged in Stockholm, sent to America, there exposed to radiation, and returned to Stockholm, when it has been found possible to determine the value of the radiation to which it had been exposed within an error of 2 per cent.

In conversation Professor Forssell expressed the opinion that with larger supplies of radium it ought to be possible to obtain results even superior to those which we had seen. He saw no reason why, with sufficient quantities of radium and with sufficient experience in its application, it ought not to be possible to deal successfully with cancer in any region of the body. And although at present he regarded carcinoma of the intestinal tract as outside the possibility of direct treatment, he was convinced that by some combination of surgery and radium it could ultimately be brought under control. He attributed the success achieved in the Stockholm Clinic to two chief factors: the combined team work of a group of men, each expert in his own department, and the extreme precision with which the whole of their work was controlled. He pointed out that they had only advanced to their present achievements by very slow degrees, and that even now their resources only allowed them to deal with cases in which, from previous experience, they could have some confidence in the results.

OUT-PATIENT DEPARTMENTS

REPORT OF COMMITTEE OF KING EDWARD'S HOSPITAL FUND

A committee, under the chairmanship of the Earl of Onslow, was appointed by the Prince of Wales, President of King Edward's Hospital Fund, to inquire into the methods in the out-patient departments of the London voluntary hospitals, and their effects on the suitability of the patients and on the time of waiting. It was held that these subjects cannot be kept distinct, since if large numbers of unsuitable cases attend there will be more crowding and therefore more waiting. The committee has now issued its report,[1] of which the following is a brief summary:

THE FACT OF WAITING

The report first discusses "the fact of waiting." The evidence comes from common knowledge, from patients and their contributory associations, and from other societies interested in them, and from the hospitals themselves, which have been giving constant attention to the question of waiting and the possible methods of reducing it. The committee concludes that there is a considerable amount of waiting in the out-patient departments, though not much in the casualty departments or in most of the special departments, but that most of the very long periods of waiting which form the subject of comment are due to medical or surgical circumstances affecting the patients concerned.

THE QUESTION OF UNDUE WAITING

The report then deals with the question whether there is unnecessary and avoidable waiting. In order to decide this the committee discusses four possible causes of waiting. It may be unavoidable where there is a large population and where staff and space are necessarily limited. It may be partly due to remediable defects in the accommodation. It may be partly due to remediable defects in the procedure. It may be partly due to the attendance of excessive numbers of patients suffering from minor ailments who could equally well be treated elsewhere and do not need the services of the highly specialized staff and equipment of an out-patient department. The report therefore discusses in turn how far the hospitals could, without hardship to patients or injury to their own efficiency, reduce the amount of waiting either by referring any considerable number of minor cases to other agencies, or by changes in their procedure, or by improvements in their accommodation. On each of these questions the evidence is largely based on action already taken or contemplated by various hospitals in their efforts to solve the problem.

[1] Report of the Committee appointed to inquire into Out-patient Methods at London Voluntary Hospitals as affecting Suitability of Patients and Time of Waiting. London: Printed and published for King Edward's Hospital Fund for London by Geo. Barber and Son Ltd. 1932. (1s. 6d. net; post free 1s. 9d.)

SUITABILITY OF PATIENTS

On the question of suitability of patients the committee finds that many of the hospitals are using their out-patient departments more and more for cases which need consultative and specialist treatment, minor cases being either dealt with in the casualty departments or referred elsewhere for treatment by general practitioners. But this can only be done if the patients can obtain this treatment at a cost within their means. The report accordingly discusses the question of financial suitability and describes the various alternative agencies which can deal with minor cases at the hospitals or elsewhere. These include the hospital consultants, the junior medical staffs, general practitioners in private or panel practice, provident or charitable dispensaries, the medical services of public assistance and other statutory authorities, and the district nursing service.

The committee suggests that co-operation between the hospitals and the other agencies should be facilitated by various improvements in the procedure for doctors' letters to hospitals and replies by the hospital consultants. Its general conclusion on this part of the inquiry is that hospitals should be encouraged to develop the consultative side of their out-patient work and the reference of non-urgent minor cases, after first attendance, to suitable agencies which provide general practitioner treatment. But this is subject to three provisos—namely, that patients who desire a second opinion but cannot pay the fees of a private consultant should have access to the hospitals, at least for one medical examination, without first having to obtain the consent of any medical practitioner; that a sufficient number of cases of all kinds should, at teaching hospitals, be available for the purposes of medical education; and that the reference of minor cases to other agencies should not be made a rigid rule, but should be introduced only gradually and applied only with gradually increasing strictness, except possibly where, as in the case of insured persons, an alternative agency has already been established, the services of which are immediately available at no further cost to the patient. The committee considers that this would reduce waiting, would facilitate the treatment of the more serious cases, and would prevent overlapping between the hospitals and the other agencies.

WAITING AS AFFECTED BY PROCEDURE

The report then deals with the question how far waiting could be reduced by changes in procedure. It describes different methods in use at different hospitals and their effects on the time taken, especially where time-saving improvements have been recently introduced. The committee first discusses the separate stages of procedure, such as arrival, registration, examination and treatment, dispensary, inquiries by almoners or inquiry officers, and the sifting of major cases from minor cases. It then considers methods of general procedure, such as the holding of different sessions for different classes of patient, or the fixing of different times of arrival for different patients during the same session, as, for example, for new patients and old patients, or for men and women. Under this last heading the committee deals at some length with the suggestion, now often made, that different patients or groups of patients should be given separate appointments, as in private practice, instead of all coming at once. This is already done for old patients in a good many special departments. There are difficulties in extending the system to general patients, but the committee considers that the subject needs more study before these difficulties are pronounced insuperable.

WAITING AS AFFECTED BY ACCOMMODATION

The report deals finally with waiting as affected by accommodation. Some hospitals are greatly hampered by inadequate out-patient premises. Several have general extension schemes which have had to be suspended during the financial crisis. But the committee quotes instances where congestion has been relieved by minor structural improvements for specific purposes, and it suggests that these also should be studied by other hospitals.

CONCLUSIONS AND RECOMMENDATIONS

The last section of the report contains a series of conclusions and recommendations based on the foregoing arguments. These are set forth in the summary which the committee appends to its report. In its final paragraphs the committee says:

We are convinced that, while part of the present waiting in the out-patient departments is inherent in the provision of hospital treatment for large populations, part of it could be saved by the methods which we have indicated. These are largely based on the experience of hospitals where waiting has actually been reduced by recent changes. Some of these time-saving changes have been made in the procedure at different stages, and some by structural alterations and additions. But the subjects which seem most to deserve study in the search for remedies for waiting are: first, in connexion with the suitability of patients, the extent to which it is possible to reduce the number of minor cases by developing the consultative part of out-patient work, though not to the undue exclusion of the other parts; and, secondly, in connexion with methods of procedure, the extent to which it is possible to depart from the principle of a single fixed hour of arrival for all patients.

The committee has been impressed by the evidence of the popularity of the hospitals, by the confidence felt by the patients and their friends in the thoroughness and efficiency of the examination and treatment provided by their medical staffs, and by the amount of attention which their committees and officers have been giving to the problem of the prevention or reduction of waiting and overcrowding in the out-patient departments. Its final recommendation is that the King's Fund should assist the hospitals in the further study of the subject with a view to definite action.

NEW YEAR HONOURS

The list of New Year honours was issued as a special supplement to the *London Gazette* on Monday, January 2nd. The names of the following members of the medical profession are included:

Baron

Sir THOMAS JEEVES HORDER, Bart., K.C.V.O., M.D., F.R.C.P., Physician-in-Ordinary to H.R.H. the Prince of Wales, Senior Physician to St. Bartholomew's Hospital.

K.C.I.E.

Major-General JOHN WALLACE DICK MEGAW, C.I.E., K.H.P., I.M.S., Director-General, Indian Medical Service.

K.C.V.O.

FREDERIC JEUNE WILLANS, C.V.O., M.R.C.S., Surgeon Apothecary to H.M. Household at Sandringham, and late Surgeon Apothecary to Queen Alexandra.

Knighthood

JOHN LAWRANCE MCKELVEY, M.B. For services to surgery in the Commonwealth of Australia.

SAN CROMBIE PO, C.B.E., M.D., formerly Municipal Commissioner, Bassein, Burma.

C.B. (Military)

Surgeon Rear-Admiral HERBERT REGINALD HARRY DENNY.

C.M.G.

WALTER BURFORD JOHNSON, M.B., West African Medical Staff, Director of Medical and Sanitary Service, Nigeria.

C.I.E.

Major-General WILLIAM CHARLES HUGHAN FORSTER, M.B., V.H.S., I.M.S., Surgeon General with the Government of Bombay.

Colonel JOHN NORMAN WALKER, I.M.S. (ret.), Director, Medical Department, and Sanitary Commissioner, His Exalted Highness the Nizam's Government, Hyderabad, Deccan.

Lieut.-Colonel ROBERT BERESFORD SEYMOUR SEWELL, I.M.S., Director, Zoological Survey of India.

C.V.O.

WILLIAM HOPE FOWLER, F.R.C.S.Ed., Consulting Radiologist, Royal Infirmary, Edinburgh.

O.B.E. (Civil)

JOHN THOMAS BRADLEY, M.D., Chief Medical Officer, Seychelles.

Miss CHARLOTTE PURNELL, M.B., M.S. For long and devoted medical work among the Arabs in Palestine and Trans-Jordan.

ERIC SLACK, M.B., Medical Officer, Leper Settlement, Botsabelo, Basutoland.

ROBERT STANLEY TAYLOR, M.D., East African Medical Service, Principal Medical Officer, Somaliland Protectorate.

O.B.E. (Military)

Surgeon Commander WILLIAM HAROLD EDGAR, M.D., R.N.

M.B.E. (Military)

Major PERCY NEIL SANDWAYS, I.M.D., British Military Hospital, Trimulgherry, India.

M.B.E. (Civil)

Subadar KISHEN SINGH, Medical Department, Kenya.

Hon. M.B.E. (Civil)

MICHAELAKI SHISHMANOGLOU, Assistant Senior Medical Officer of Health, Palestine.

Kaisar-i-Hind Medal

Miss CHARLOTTE ROSE GREENFIELD, Medical Officer in charge of St. Margaret's Hospital, Poona, Bombay.

ROBERT HAROLD HULL GOHEEN, medical missionary in charge of the American Presbyterian Mission Hospital at Vengurla, Ratnagiri District, Bombay.

The Right Rev. KENNETH WILLIAM STEWART KENNEDY, M.B., B.Ch., D.D., Bishop of Chota Nagpur, Bihar and Orissa.

The following promotions are also announced:

Royal Navy

Surgeon Commanders to Surgeon Captains: WILLIAM H. EDGAR, ARTHUR G. V. FRENCH, HORACE E. R. STEPHENS, O.B.E.

Royal Naval Volunteer Reserve

Surgeon Commander to Surgeon Captain: THOMAS TURNER, V.D.

Surgeon Lieut. Commanders to Surgeon Commanders: THOMAS W. DRUMMOND, WILLIAM F. W. BETENSON.

The honour of Knighthood has also been conferred upon Professor FREDERICK T. G. HOBDAY, C.M.G., F.R.C.V.S., Principal and Dean of the Royal Veterinary College.

The distinction C.B.E. (Civil) has been bestowed upon Mrs. ALICE BAKER, one of the founders of the Thomas Baker, Alice Baker, and Eleanor Shaw Medical Research Institute, Melbourne, Commonwealth of Australia.

South Africa

[FROM OUR CORRESPONDENT IN PRETORIA]

League of Nations Regional Health Conference

A conference arranged at the request of the Union Government by the Health Organization of the League of Nations to discuss those health problems arising as the result of rapidly increasing air transport, in particular the possibility of spread of yellow fever, was opened at Capetown on November 15th, 1932. Medical representatives from the various African States and from British India attended, and the League of Nations was represented by Sir George Buchanan. While the agenda was very largely occupied with the problem of yellow fever, other public health problems of inter-State importance were discussed, such as plague, which is endemic among wild rodents of many of the African States, small-pox, which is periodically conveyed to the eastern portion of the continent by immigrants from India, and the difficulties of providing adequate medical and health services in the rural native reserve areas. The administrator of Cape Province, Mr. Conradie, in welcoming the delegates, pointed out the urgency of holding such a conference to examine questions relating to public health administration and protection

against epidemic diseases. The Health Organization of the League of Nations had already rendered conspicuous service in investigating the incidence of epidemic diseases, and this conference would be another step in the attempt to solve the very complex problems facing health experts in Southern and Central Africa. The discussions might result in determining not only the most effective measures of combating the actual inroads of disease, but also of fighting existing infection in the country. Dr. Park of Singapore, in replying to the welcome, explained the functions of the Health Section of the League, and emphasized the value of these regional conferences, which went a long way towards removing international misunderstandings. Sir George Buchanan referred to the advantages to be gained from an interchange of the experiences of different countries in combating various diseases. In matters of health they should endeavour to remove frontiers, so that one country could know what its neighbour was doing to fight disease. Geneva could not be regarded as a repository of all the intelligence of the world, and regional conferences were therefore essential for the exchange of information. Mr. Conradie had said that the Covenant of the League, in addition to providing for international co-operation, included a declaration to the effect that members wished to take steps for the prevention and control of disease. The League provided for the organization of international co-operation in the domain of public health. One of the earliest problems had been the establishment of a clearing-house for the receipt and distribution of information about epidemic diseases throughout the world. This work had been developed to such an extent that conditions in almost every country were made known to all health administrations. The investigations undertaken by the Health Committee of the League had been most successful. The principal features of the work had been the development of closer co-operation, and the gradual accumulation of information about health matters in various countries and the measures applied to combat disease.

Annual Report of Public Health Department

In his report of the Union Health Department for the year ended June 30th, 1932, Sir Edward Thornton records with great regret the retirement of Dr. J. A. Mitchell, his predecessor in the combined post of Secretary for Public Health and Chief Medical Officer. Dr. Mitchell's health broke down in 1930 at Bangkok, where he was representing the Union Government at a meeting of the Leprosy Commission of the League of Nations Health Organization. He resumed duty in August, 1931, but, owing to continued ill-health, found it necessary permanently to relinquish his office. The report states that the financial stringency has adversely affected the activities of the Department, which has, nevertheless, been able to carry out all its functions on a smaller scale. The European vital statistics (the only ones recorded) were very satisfactory. The general death rate (9.37 per 1,000 population) and the infantile mortality rate (63 per 1,000 live births) are the lowest so far recorded for the Union. Owing to lack of funds the non-European population has not been enumerated since 1921, although the European population has been enumerated twice during that time. This absence of accurate statistical information regarding the native population greatly hinders health administration.

The epidemic of malaria which occurred in Natal during the autumn (March and April) was the worst ever experienced there. The summer started with a drought, which denuded large areas of vegetation, so that the late rains produced the unshaded puddles favoured by the malaria vector, the *Anopheles costalis*. There were only sporadic cases during January and February, but towards the end of March the number increased, the epidemic reaching its height in April. The report reiterates the lessons to be learnt from this epidemic—namely, that malaria is a local disease requiring to be combated by measures which can only be effectively enforced by a properly constituted local authority thoroughly alive to the menace. The unusually high mortality among the Bantus is attributed to massive infection as the result of *costalis* prevalence and to the fact that many of the districts had been famine-stricken owing to the drought. The mal-nourished children could offer little resistance, and the mortality among them was high. Quinine was distributed on an extensive scale by the native malaria assistants employed by the Department, who visited 30,508 sick natives. The drug actually reached very many more, since it was carried by relatives to less accessible parts. The mortality due to the epidemic cannot be ascertained accurately, owing to the absence of any system of registration of native deaths. It is estimated, however, that there were 10,000 deaths among a population in the affected areas of well under a million.

The plague incidence among the human population was low—twenty-two cases, of which sixteen were fatal; all the cases occurred in the Orange Free State. As usual, the infection was traced to veld rodents. The presence of infection among these animals over wide stretches of country necessitates an alert policy on the part of the Government. Careful surveys are continually being carried out by a staff of inspectors, and a strict watch is kept on the spreading waves of infection among rodents. The rabies endemic among certain wild carnivora in the northern provinces also requires watchfulness. Propaganda has been fairly effective, and persons bitten by such animals report for treatment; none of the persons treated developed symptoms. Two fatal cases of human rabies occurred during the year, one a European male adult who was bitten in the hand by a yellow mongoose, the other a native male adult bitten on the lip by a genet cat. In both cases, as was subsequently ascertained, the victim had been bitten three weeks prior to the onset of symptoms; death occurred six days later.

"Bilharzia camps" for children were established as in previous years in parts of the Transvaal where the snails are infested with the schistosome. Fouadin and sodium antimony tartrate were used for treatment. The former was found to give quicker results, to be easier to administer, and complications were absent. The objection to its general use was one of expense; the cost of the fouadin required to cure one patient was equal to the cost of treating fifty with sodium antimony tartrate. In addition to the treatment camps, farm schools in badly endemic areas were given financial assistance in the erection of bilharzia-free swimming baths. Typhoid continues to be unduly prevalent. Although notifications average 4,000 yearly, the actual incidence is certainly much higher. Owing to imperfect notification, particularly among the native population, and to the fact that the causative bacillus not infrequently produces a condition not recognizable apart from laboratory tests, precise figures cannot be obtained. It is probable also that in Bantus the usual clinical picture is, more often than not, absent. The Department publishes annually a "black list" of the urban local authorities with the highest incidence per 1,000 of population, on the grounds that the prevalence of the disease is largely due to preventable local insanitation. The policy of "probationally discharging" those lepers in whom the disease is considered by a medical board to be "arrested and non-infective" has continued to give satisfactory results. The news appears to be spreading among the native population that entering an institution does not necessarily involve life-long incarceration, particularly if the treatment offered is accepted. Of 2,582 lepers probationally discharged since this policy was

adopted in 1923, only 199 have had to be readmitted owing to recrudescence. During the year Dr. Wade, chief pathologist to the Culion Leper Settlement, Philippine Islands, visited South Africa in his capacity of secretary to the Leonard Wood Memorial Fund. The terminology suggested at the Culion Leprosy Conference was discussed, but it was pointed out to Dr. Wade that certain cases common in South Africa did not appear to fit in with that classification. Dr. Wade was given all facilities for inquiring into this matter. The incidence of typhus continues to be high ; 1,550 cases were reported during the year, chiefly from the native territories of the Cape. The infection is, however, of a mild form locally, and mortality is low. The mild nature of the disease has raised doubts in the minds of observers, and it is thought that some of the outbreaks may be due to a flea-borne, typhus-like disease rather than to true typhus.

Birth control clinics supported by voluntary effort have been started in Johannesburg, Capetown, and Pretoria. The instruction is given to those mothers for whom it is considered necessary to prevent further pregnancies or to have greater intervals between confinements. The serious shortage of trained and certificated nurses, particularly in the rural areas, continues.

Scotland

St. Andrews Clinical Research Institute

The annual report of the Sir James Mackenzie Institute for Clinical Research shows that a considerable number of continuous health records from birth onwards have been collected during the thirteen years of existence of the institute. It is believed that in about thirty years a great wealth of medical knowledge concerning the life-histories of health and illness will have been collected, and will be available for the benefit of the country. The council expresses the opinion that this object is worthy of national support, and that it would be a misfortune if the records had to be broken off or terminated. Special attention is therefore drawn to the finances of the institute. The capital sum available amounts to £10,999, of which only £3,218 is entailed. The income from investments and subscriptions in the current year will not exceed £718, although at least £1,400 is required for maintenance. It would be possible to continue to meet expenditure for about two years by drawing on unentailed capital, but this would be an unwise procedure. Under these circumstances the council feels it must seriously consider closing the institute unless an increase of income of at least £750 a year is assured. It may be added that the clinical members of the staff give their services voluntarily, and the amount expended on salaries and wages is incurred in the employment of the laboratory, radiological, and clerical staff.

Vital Statistics of Scotland

The report of the Registrar-General for Scotland for 1931 shows that the birth rate was the lowest on record, that there was a slight further improvement in the death rate, while the infantile mortality rate had only once been lower. The mortality from the principal epidemic diseases was low, that from measles especially improved. Births registered during the year numbered 92,220, or 2,329 fewer than in the previous year ; this was equivalent to a rate of 19.04 per 1,000 of the population, and was only about half of the maximum Scottish birth rate of 35.62 registered in 1876. There were 64,229 deaths in the year, giving a rate of 13.26 per 1,000 of population, the lowest recorded except for the years 1923 and 1926, when the rates were 12.95 and 13.11 respectively. Deaths of infants under 1 year numbered 7,544, or 81.8 per 1,000 births. Influenza was responsible for 1,270 deaths, whooping-cough for 957, measles 641, diphtheria 356, cerebro-spinal fever 290, scarlet fever 161, typhoid 31, erysipelas 174, encephalitis lethargica 99, and poliomyelitis 15. There was no death from small-pox, and only one from typhus. Deaths from all forms of tuberculosis numbered 4,205, the lowest figure yet recorded ; the death rate is now less than one-quarter of the mean annual rate which prevailed in the period 1861–70. The death rate from phthisis varies with age, declining after infancy to its lowest at 5 to 9 years, rapidly increasing thereafter to its maximum at 15 to 24 years for females and 35 to 44 years for males ; over 35, the male death rate from this cause is almost twice as high as the female. Malignant disease accounted for 7,158 deaths, the organs affected being, in order of frequency, the stomach, liver, peritoneum, intestine, rectum, buccal cavity, and genito-urinary system. The age of greatest frequency was 65 to 70 in males and 70 to 75 in females. Considerable attention is paid in the report to an analysis of mortality in childbirth. While the mortality rate from puerperal causes in 1855 had been 4.9 per 1,000 births, with 1.7 due to puerperal sepsis and 3.2 to other causes, the rate in 1931 was 5.9, including 2.2 due to sepsis and 3.7 to other causes. There had been a general trend upwards of puerperal mortality in each decennium from the beginning of registration, except 1895 to 1904, which showed the lowest rate ever recorded in the country of 4.6. The year 1931, however, had shown an improvement in a rate of 5.9 as compared with 6.9 in 1930. The chief causes of maternal mortality in the past ten years had been puerperal sepsis 30.76 per cent. of deaths, eclampsia 16.59 per cent., and haemorrhage 11.98 per cent. Mortality of women from all puerperal causes in Scotland is 50 per cent. higher than in England and Wales. It is suggested, however, that this discrepancy is largely due to differences in classification. The maternal mortality rate was found to differ widely in various counties of Scotland, the rates ranging from 7.98 and 7.72 in Wigtown and Orkney down to 2.46 and 2.55 in Nairn and Bute. Deaths from sepsis showed considerable seasonal variation, the mortality being higher in winter and spring than in the summer and autumn months. An appendix deals with the vaccination of children born in Scotland in 1930. Of 94,571 children born in 1930, 6,242 died before reaching the age of statutory vaccination, leaving 88,329, of whom 47,796, or 54.11 per cent., were certified to have been successfully vaccinated ; 34,079, or 38.58 per cent., of the total were unvaccinated by reason of a declaration of conscientious objection. It is pointed out that prior to the Vaccination (Scotland) Act, 1907, more than 91 per cent. of children born in Scotland were vaccinated ; this percentage has steadily decreased each year, except in 1920, when there was an epidemic of small-pox in Glasgow and the percentage rose to 70.54. Another appendix analyses the mortality from diabetes. The crude death rate from diabetes in Scotland at the beginning of the present century was 67 per million ; this steadily increased until, in 1915, it was 113. During the war the rate fell to 83 ; and in 1922 it had increased to 108, being steadily more common in females than in males, but the following three years, after the introduction of insulin, saw a fall to 93 per million in 1925, and by 1931 it had again increased to 175 per million, the total number of deaths in this year being 660, or 56 more than in 1930. There is a steady increase in the death rate of diabetics from infancy to old age. The report states that pernicious anaemia is a comparatively rare cause of death under 35 ; thereafter the death rate increases in frequency with age in both sexes up to 75 years, females showing a much heavier death rate than males. During

1931, 285 deaths were attributed to this cause, and this compares very favourably with the figures for previous years. The improvement is attributed to new methods of therapy.

Glasgow Western Infirmary

At the annual meeting of the Western Infirmary, Glasgow, Colonel J. A. Roxburgh, chairman of the Governors, stated that the institution had been fully occupied throughout the past year, and the waiting list had not diminished. The auxiliary hospital at the David Elder Infirmary, which was opened in January, 1928, for surgical cases, had dealt with over 3,000 cases during the year. The Tennent Memorial Ophthalmological Department, for which the plans had been adjusted, would be begun early in 1933. A sum of £6,500 had been received from the trustees of the late Dr. and Mrs. Fullerton of Arran, and with this the Governors proposed to erect a training school for nurses, which would be ready within six months. Workmen's contributions would unfortunately be smaller on account of the depression in industry, and several large donations of previous years had been much reduced. Grateful patients had given £1,674, and one contributor had sent £1,500 in recognition of the treatment of a number of his employees in the institution. There would be a deficit on ordinary revenue for the year of not less than £12,500, the same as for the preceding year; this sum would have to be met from legacies.

Glasgow Orthopaedic Work

Presiding at the annual meeting of the Royal Hospital for Sick Children, Glasgow, Lord Provost A. B. Swan announced that the new orthopaedic department, which is to be built at a cost of £50,000, will include several small wards with cots—erected in such a way as to permit open-air treatment—a gymnasium, and rooms with appliances for remedial exercises, electrical treatment, light treatment, and hydrotherapy. Comparing the work of the hospital to-day with that of fifty years ago the chairman stated that in 1882, the first year of its existence, the hospital dealt with 260 cases, whereas 5,626 passed through the wards during the last year. The report for the past year showed an excess of expenditure over income of about £1,100. The number of out-patients treated had been 20,000, with a total of visits amounting to 104,113. The average daily number of children in the wards had been 244, the total available cots being 270.

Aberdeen Medico-Chirurgical Society

The annual commemorative founders' dinner of the Aberdeen Medico-Chirurgical Society was held on December 10th, 1932, under the presidency of Dr. W. Clark Souter. This society was founded in 1789 by twelve medical students at Marischal College, of whom James McGrigor, later principal medical officer to the Duke of Wellington, was the leading spirit. At the dinner, after the usual loyal toasts, Emeritus Professor J. A. MacWilliam proposed "The Founders of the Society," and Mr. Alexander Mitchell gave the toast of "The Guests," for whom Major M. M. Cruickshank, I.M.S., replied.

Proposed New Edinburgh Hospitals

At a meeting of the Public Health Committee of Edinburgh Town Council on December 20th last, it was decided to take no action on the motion that a maternity hospital should be provided in Leith to accommodate the thirty to forty cases which had to be removed each week to the Royal Maternity Hospital in Edinburgh or the Elsie Inglis Memorial Hospital. A good maternity service was provided in Leith by nurses connected with the Royal Maternity Hospital, and accommodation was available at the Council's Western General Hospital recently taken over by the local authority. The city architect submitted a report on the area of twenty-eight acres in the neighbourhood of the Colinton Mains Hospital for Infectious Diseases, which it is proposed to reserve for a general hospital. The site would provide accommodation for a hospital of 500 beds, with the usual administrative and special departments, and with sufficient grounds for recreation and isolation of the hospital. The Public Health Committee approved the report, and also set apart an area of some eight acres adjoining Redford Barracks in the neighbourhood for a hospital which the War Department had proposed to build. Tenders were submitted and approved for the erection of two more blocks at Gogarburn, certified institution for mental defectives, at a cost of about £9,000.

Ireland

Hospital Sweepstakes (Irish Free State)

The report of the Committee of Reference for hospital sweepstakes has just been published. It sanctions the participation of forty-eight hospitals in the Grand National Sweepstake. These hospitals claimed £7,736,296, and are awarded £4,809,457. Increases to forty-four hospitals represent £851,212, of which £647,186 is for endowments. The gross total award for endowment is thus increased to £2,878,147, as against claims amounting to £4,586,270. There are, it is understood, seven sweepstakes to come before the Act expires. The Grand National, 1932, made available £470,000, and, assuming that a sum of £500,000 for each of the seven other sweepstakes is realized, the total will be £3,970,000. There would still remain of the present estimated needs of forty-eight hospitals an amount unprovided for of £939,457. The report criticizes hospital administration generally, and states that the greatest possible advantages and economies would result from the co-ordination, as far as practicable, of the services of the voluntary hospitals. The sacrifices which this would entail would be outweighed by an improved service to the sick, and by increased opportunities for the teaching, study, and prevention of disease. Commenting on certain defects in the present system, the report states that many of the plans submitted for new buildings show a lack of familiarity with the needs of a hospital. There is a tendency to introduce unnecessary departments and equipment which, in some cases, would be sufficient to cater for twice, or even three times, the number of patients for whom they are claimed. Any unnecessary expenditure on buildings must automatically reduce the amount available for endowment, to the detriment of both patients and staffs of the hospitals.

Allocations for Clinical Research

The report states that a scheme is under consideration whereby a joint proposal will be presented to the committee at an early date on behalf of a number of Dublin hospitals for allocation of a sum to build, equip, and endow an institute for clinical research. As indicated in the previous report of the committee a scheme for co-ordinated research is considered necessary and desirable if clinical opportunities offered by reconstituted hospitals are to be utilized to the greatest advantage. It is the absence of facilities for continuous research in clinical fields which makes it necessary for students to go abroad. There is much to be said for the belief that on the restoration of a lost tradition in this field the future of Irish medicine and hospitalization to a large measure depends. The promoters of the new scheme will probably not lose sight of the desirability of co-operation between university laboratories and hospital workers, and

the report considers that the proposals should include facilities to research workers by the medical staffs of the hospitals. The total sum involved would be not less than £250,000.

Treatment of Children's Diseases

Special attention is given to the question of children's diseases. The treatment provided at present for the illegitimate and mentally defective child, as well as for the deaf, dumb, blind, and crippled, is inadequate. It would be impossible to expect that any one of the existing children's hospitals should embark on a comprehensive scheme embracing all the activities which make for the betterment of child health and welfare. Such hospitals are already providing for the treatment of ordinary children's diseases, but the main problem is still untouched. There is a lack of facilities for research, and there are gaps in the medical knowledge of children's diseases. The various institutions concerned with child welfare are not unified, and the existing extern departments are unsuitable. It is in the development of outpatient departments in the children's hospitals that the most practical solution of the problem will be found. The report suggests that a central clinical extern should be established, which would provide for new classifications, opportunities for research, and educational facilities for doctors and students. The clinic should be erected on a central site, and be sufficiently large to deal with the aggregate total per day of those children attending the city hospital dispensaries. Provision should be made for medical, surgical, electrical, scientific, and dental treatment.

Reference is made in the report to the proposals of some of the larger hospitals to provide more facilities for tuberculous patients, and comments are made on the direction which such schemes should take. Cancer treatment, obstetrics, and nursing services are also dealt with.

Memorial to Dr. Walter Stevenson

A tablet in memory of the late Dr. Walter C. Stevenson was recently unveiled at the St. John Ambulance Hall, Dublin, in the presence of his three sons and a number of members of the brigade and their friends. Sir John Lumsden, who performed the ceremony, said that before the Boer war Dr. Stevenson was interested in the work of the St. John Ambulance Association, and in 1910 he succeeded the late Dr. Dallas Pratt as honorary secretary, a position he held until his death. He gave an enormous amount of his time to teaching and examining, and to the compilation of the official records of the Irish centre. In 1914 he became a district surgeon of the brigade, and in 1919 the Grand Prior appointed him Knight of Grace of the Order. Sir John referred to the wonderful pioneer work Dr. Stevenson had done in connexion with x rays and radium, and spoke of his kindness, sympathy, and modesty. Professor R. J. Rowlette, who said he had known Walter Stevenson since his student days, sketched the history of his work, in co-operation with Professor Joly, in the field of radium, and particularly in the application of radium to the treatment of disease. He said that the method they introduced about twenty years ago was quickly taken up in Continental countries. So much greater was the publicity given to the treatment abroad that it became known as the "Brussels" method, later as the "Brussels" or "Dublin" method. Dr. Stevenson's pioneer work had given, and would give, relief to thousands of people all over the world.

Ulster Nursing Council

At a recent meeting of the Joint Nursing and Midwives' Council for Northern Ireland Miss A. E. Musson was re-elected to act on the Northern Ireland Executive Committee of the Queen's Institute of District Nursing. In response to a letter from the medical officers of the Belfast Infirmary, stating that the infirmary would be in great difficulties if only two preliminary examinations were held during the year, it was agreed that an additional examination should be held, commencing on May 23rd. A report on the proceedings at the conference of representatives of the General Nursing Council for England and Wales, the General Nursing Council for Scotland, and the Joint Nursing and Midwives' Council, held in Edinburgh on November 28th, 1932, to consider the question of adopting a minimum educational standard for nurses taking the State examinations and of dividing the preliminary into two parts, was given by Miss A. Curtin and Miss A. E. Musson. It was agreed that copies of the minutes of proceedings forwarded by the General Nursing Council for Scotland should be circulated to the council, and the matter brought up for further discussion at a future meeting.

Extension of Mental Hospital

The report of the medical superintendent to the committee of management of Belfast Mental Hospital shows that there has been a large increase in the number of patients during the last few years, although there has actually been a decrease of seven since the last meeting of the committee. The average number of patients for the year 1927–8 was 1,201; it is now 1,406, an increase of 205. The institution, the report states, is being used as a clearing-house. The Ministry has ruled that it must admit all cases. Its function is to take people domiciled elsewhere until their proper place is discovered and they can be transferred; it has to take children, and old men who have become childish. Of the 1,406 patients admitted, 724 were males and 682 females. Since the last meeting nineteen males and twenty-one females have been admitted, while fifteen males and fifteen females have been discharged. Eight males and nine females have died. Four of the total number of patients have been received as voluntary cases, and eight as temporary; they were not, therefore, certified to be of unsound mind.

England and Wales

Treloar Cripples' Hospital

In the annual report of the Lord Mayor Treloar Hospital at Alton, Sir Henry Gauvain comments on the increasing proportion of general orthopaedic cases admitted to the hospital each year, and he attributes this to the work of the school medical and the maternity and child welfare services. At the same time there is a steady fall in the incidence of surgical tuberculosis, so that it is possible to adjust hospital accommodation to the new demands. Clinics at Alton, Andover, Eastleigh, Havant, Portsmouth, and Southampton are conducted from the Alton hospital, and clinics working in association with the hospital and conducted by surgeons attached to the staff have also been established at Basingstoke, Farnborough, and Fleet. New hospital buildings are now being erected at Alton, and those which are complete have proved to be admirably designed for their purpose. The seaside branch of the hospital at Hayling Island has done excellent work during the year. The hospital land includes over a mile of beach, and is remote from any town. The building faces south-east, from which quarter the wind rarely blows, and the rainfall at Hayling Island is the lowest in the South of England. Experience has shown that the strong stimuli of sun, sea breezes, and bathing cannot be tolerated by weakly or cachectic children, or sick children under the age of 5. Children who are likely to benefit by treatment at the seaside are those with good constitutions, who have responded well to sun treatment inland, but in whom further progress is

a way as to avoid general reactions. Dr. Gillespie's method seems to be that at first he tries to secure some reaction, then to reduce his dose if the reaction first produced be severe [*sic*], and then to find the highest rate of increase which can be tolerated without reaction. My only comment is that my method, if irrational and absurd in Dr. Gillespie's opinion, is at least consistent.

Dr. Camac Wilkinson takes me to task for many things, the most important being that in his opinion my way of giving tuberculin, even in the maximum doses to which I am accustomed to proceed, is useless. I should like to remind him that there are observers of this disease as earnest and as experienced in assessing methods of treatment as himself, who have given up the use of tuberculin entirely, on the grounds that at best it is useless and at worst it may be harmful. I gather that, in Dr. Camac Wilkinson's opinion, I ought to give up tuberculin altogether unless I am prepared to adopt his method.

The tuberculin problem is, in my judgement, not one for platform discussion, but for critical analysis of individual experience and for reasoned criticism of different methods and of collected statistics. My opinion of tuberculin remains what it has always been—that I am sure it can be harmful, while I *think* in suitably selected medical cases it can be useful, as well as in the surgical localizations of the disease. If I am ever persuaded to give up its use I think it will be the arguments of its exponents rather than those of its critics which will be responsible. One point I may concede Dr. Camac Wilkinson, and that is that the use of liquid measure in describing dosage is more scientific, and possibly more accurate, than that mentioned in my paper.—I am, etc.,

London, W.1, Jan. 2nd. R. A. YOUNG.

The Biochemical Syndrome of Uraemia

SIR,—In his very interesting paper, in the *Journal* of December 24th, 1932, on uraemia Dr. Geoffrey Thompson tells us that his object was "to distinguish the true biochemical syndrome of uraemia from certain allied conditions." He compares the clinical phenomena presented by his patient, who unfortunately suffered from a hopeless rupture of his only kidney, which was removed, with those presented by patients with certain diseases "accompanied by a functional disturbance of the kidney, which tends, if severe, to end in a condition of uraemia apparently similar to that following total nephrectomy in animals"—and, amongst others, he mentions acute nephritis. In his case the blood pressure remained low throughout, and even fell below normal; there was no oedema; and, though fibrillar contractions of muscles occurred, there was no convulsive phenomenon. He concludes that these differences—which seem, rather, additions—are to be attributed to extrarenal factors, "which usually accompany the true biochemical syndrome"; whereas, according to him, "the latter varies in degree only, but not in kind, from case to case."

With this conclusion I find myself, I think, in complete agreement. But what are these extrarenal factors? The most significant remark in the report bearing on this point is the statement that the patient "received nothing by mouth except water and calcium chloride." Nor was any protein administered in any other way. Only "forty ounces of 5 per cent. glucose in saline were given by rectum each day." Headache, drowsiness, and marked vomiting, with death on the tenth day, ensued. But if patients with acute nephritis were treated in this way, what would happen? Possibly, if such treatment were given at the outset, the patients would rapidly revert to a state similar to that presented by Dr. Thompson's case—a lowering of the blood pressure, the disappearance of the oedema, and the absence of convulsive phenomena would be noted. And since in such cases the kidneys, however impaired, still exist, the probability is that the renal function would be rapidly restored, the patients getting well.

The difficulty is that acute nephritis is only diagnosed when oedema already exists: it is the oedema which causes one to examine the urine and to take the blood pressure—to diagnose the case. Two questions arise: (1) What is the state of the kidney immediately antecedent to the syndrome recognized as acute nephritis? (2) What is the cause of the oedema and other signs? Most people think that the acute nephritis is due to a toxin, and that a toxin is in the blood; and to this may be attributed the symptoms caused by the extrarenal forces. But, as someone at the recent meeting of the Royal Society of Medicine reminded the audience, the toxic hypothesis of acute nephritis has not yet been proved. Possibly the disease may be produced mechanically—as in pregnancy—by a blocking of uriniferous tubules in the medulla, by turgescence of this part. The influence of cold, which by constricting the cutaneous arterioles of necessity determines a greater visceral supply, must be considered. Trench nephritis, in which de Wesselow failed to find streptococci in the urine, is an example. And the effect of a contemporaneous diuresis—or the need for one—must be simultaneously kept in mind.

Thus, the question resolves itself into another. What would happen if the kidneys of a patient became blocked in such a manner—that is, if the individual got into a state comparable with that presented by Dr. Thompson's patient—and continued eating and working? Would the blood pressure go up? Would oedema occur? Would convulsions be likely? The effect of such a disturbance of the renal circulation must necessarily affect the blood flow through other parts. The blood flow through the liver must become increased—even to the extent of the systemic blood being contaminated by portal blood, insufficiently purified. Naturally, the rapidity (the duration) of the process must reflect itself in the blood changes found—in the non-protein-nitrogen ammonia urea content.—I am, etc.,

Rugby, Dec. 24th, 1932. R. H. PARAMORE, F.R.C.S.

Epidemiology

SIR,—Professor Greenwood's letter (December 24th, 1932, p. 1164) comes most appropriately at this season of peace and good will, and I hope you will allow me to thank him for his notes on my appreciation (December 10th, 1932, p. 1061) of his book. His first and second annotations satisfactorily dispose of any possible misunderstandings, and as, here, I may have been (in all innocence) at fault, I humbly express regret, but the third annotation, on Freind's criticism, must clearly be held, in Oliver Goldsmith's phrase, to constitute "the cream of the correspondence."

I threaded my way rather anxiously through Professor Greenwood's comments on "Sydenham's own testimony," as cited in my list of references to the *Medical Observations*, and, when I realized they were being tackled seriatim, I was stirred with an enthusiasm resembling that of little Mr Perker of the *Pickwick Papers*, when he saw his candidate for Parliament actually kissing, one after another, the carefully selected babies in arms, whom he had only been expected to put on the head. And then, alas! after murmuring to myself, "He has studied one reference, he has studied another. I found he was not studying them all, and then followed his conclusion: "Freind, who was a clinician, is right." Sydenham, however, was not only a [illegible] a clinician himself, he was even acclaimed as "The

founder of epidemiology," and I venture, therefore, to direct attention once again to my final citation (*Medical Observations*, V, vi, 8), which is, I believe, especially deserving of study in connexion with Freind's criticism. We read (loc. cit.): "Now, however high we may put the difficulty—even if we rank it among the impossibilities—of accurately distinguishing a new fever, immediately upon its appearance, we may still take indications as to the treatment from the *juvantia* and *laedentia*"—that is, if diagnosis be at fault, there is still the possibility of treating the symptoms. And then, too, there are the significant facts, never to be forgotten, noted in the Herter Lectures: first, "Sydenham's conception of an epidemical succession . . . was never so forcibly and magnificently expressed as by him"; and, secondly, "Where the clinical feature is involvement of the nervous system and pandemic influenza; there exists, not a pathological bond in the narrow sense, but an epidemiological affinity as perhaps Sydenham surmised."

Surely, in the light of all these findings, students of the Herter Lectures—and may there be many of them (be they clinicians, bacteriologists, epidemiologists, disciples of Freind, of Koch, or of Sydenham)—may now say to one another, in Sir W. S. Gilbert's well-known words, "I am right, and you are right, and all is right as right can be."—I am, etc.,

London, N.W.5, Dec. 26th, 1932. W. H. HAMER.

Principles of Obstetric Practice

SIR,—Dame Louise McIlroy, in her admirable paper on the above subject in the *Journal* of December 24th, 1932 (p. 1158), hits the nail on the head when she says: "I have always held the opinion that the responsibility for maternal welfare in this country lies in the hands of the family doctor; especially is this the case in country and small town areas." My only comment is that the word "should" ought to be placed before "lies" (reading "should lie"). At the present time a large sum of public money is being spent on ante-natal clinics, which are visited periodically by a medical practitioner, who watches the course of pregnancy up to the time of the onset of labour. This (presumably expert) obstetrician is nowhere to be found when labour starts and an unforeseen complication becomes apparent. The general practitioner is called from his bed (while the expert sleeps) and is expected to overcome any difficulty he may be presented with. If he fails, he is blamed; if successful, it was only his duty, and he gets little thanks.

During the time I was resident medical officer of the Newcastle-upon-Tyne Maternity Hospital I was struck by the frequency with which the doctor's letter, which arrived with an emergency case, began: "I saw this patient for the first time at . . . She had been in labour since . . . and on examination I found . . ."

How much better it would be for the local authorities, instead of spending money multiplying their clinics, which are in unfair competition with the general practitioner, and which can never be utilized by women in the rural districts, to reduce the number and staff them with sound, practical obstetricians, who would act in consultation with the practitioner in cases of difficulty referred by him.

At the present time the working-class woman receives £2 after parturition (£4 if both husband and wife are insured) on production of a certificate given by a medical practitioner or midwife. Would it not be possible to frame a scheme making it obligatory for a woman, in order to qualify for this benefit, to report to a medical practitioner at, say, the fifth or sixth month? The practitioner would be able to give her ante-natal supervision, and, in cases of doubt or difficulty, he could refer her to the central clinic for expert advice. Such a scheme would enable the local authorities to do away with their clinics, and the money saved could be devoted towards the remuneration of practitioners for their ante-natal work. I do not propose to enter into the financial questions of this subject. I am no financial expert, but the remuneration of the general practitioner and expert should be adequate; otherwise the scheme would not be a success. The most important benefit to be derived from such a scheme would be the increased interest and pride of the medical practitioner in his midwifery, which, in existing circumstances, is being crushed out of him.

In conclusion, I consider Dame Louise McIlroy's suggestion for refresher lectures excellent. The only comments I would make are: (1) lectures without clinical work are not of great value; (2) unless one could be assured that all practitioners could (and would) attend, the scheme would not be a great success, the strength of the chain being that of its weakest link.—I am, etc.,

Epsom, Dec. 24th, 1932. TERENCE G. ROBINSON.

Maternal Morbidity

SIR,—The final report of the Departmental Committee on Maternal Mortality and Morbidity[1] contains some interesting facts. The broad conclusion arrived at—that at least one-half of the maternal deaths are due to a departure from an arbitrary standard of midwifery—is not, I think, very convincing. I do not mean to imply that this standard is not essential if we hope to reduce maternal morbidity, but that even if there is a strict adherence to this standard the morbidity will not be reduced to the extent the committee hopes. I believe other factors are equally important.

Of the 4,800 cases enumerated in Table I, roughly 40 per cent. are due to sepsis, 20 per cent. to surgical emergencies arising during labour, and 40 per cent. to factors mainly arising before the onset of labour—such as eclampsia and abortion. Of the septic cases more than 85 per cent. are due to *Streptococcus haemolyticus*, which is found in the genital tract of many women who do not become septic. Also 50 per cent. of septic cases occurred in spontaneous labour. It seems to me, therefore, that the determining cause is the susceptibility of the mother, and the best method of combating it is by the immunization of susceptible mothers in the same way that susceptible members of the staffs of fever hospitals are detected and protected. Of surgical emergencies many must be due to severe and mild forms of rickets, and we must look to the elimination of rickets as much as to the treatment of these cases in hospitals or nursing homes. Of 162 eclamptic cases, sixty-two occurred without any previous albuminuria, and we must wait for a greater knowledge of the prophylaxis of toxaemic conditions before these can be materially reduced. The prevention of abortion must be the greatest problem, and even if compulsory notification of conception were practicable it would, I think, avail little.

I think attention should be focused on these conditions as much as on the primary avoidable factors before we can hope for a great reduction in maternal morbidity.—I am, etc.,

Stechford, Dec. 17th, 1932. H. G. LANGDALE-SMITH.

SIR,—May I assure Dr. Kathleen Vaughan that it was far from my mind to raise any objection to her theses? On the other hand, I had thought to support one of them by giving what seems to me an anthropological explanation for some, at least, of the instances of incompatibility between maternal pelvic and foetal head form. I am, of course, well aware of the mechanism of occipito-anterior

[1] *British Medical Journal*, August 13th, 1932, p. 327.

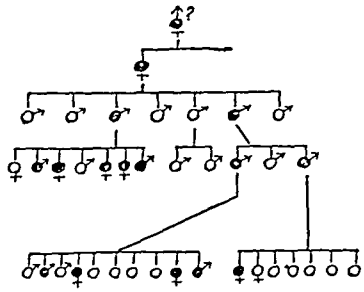
presentation, said by us to be "normal," although, for some Asiatic heads, a vertex presentation would seem to be more advantageous! But I remain under the impression that flexion and rotation, in Western Europe, are conduced to by harmony and interfered with by disharmony between the mother's pelvis and the child's head. Nor can I believe that the variation, throughout the world, of female pelvic form in correlation with infantile head form is without significance in the economy of Nature. In this connexion two papers occur to memory as interesting: the first, by Acosta and Calderon (mentioned in the *Lancet*, 1919, ii, 988), the second, by Rummell (abstracted in the *Epitome* of the *British Medical Journal*, November 16th, 1929, para. 452). Of course, too, the relation between the pelvis of a "healthy outdoor native woman" and the head of her "child by a European father" depends very much upon the racial type of the native woman and the morphology of the European father. We are apt to forget that a very large proportion of "Europeans" are very brachycephalic indeed. I do hope that Dr. Vaughan may come to admit that anthropological considerations are perhaps more worthy of attention than, I fear, she is at present inclined to concede them. Sound propositions, such as hers, so often fail to achieve due recognition by reason of the quite unnecessary exclusion of adjuvant or even corrective notions.—I am, etc.,

London, W.1, Dec. 24th, 1932. F. G. CROOKSHANK.

Monilethrix

SIR,—It seems possible that the Scottish family comprising twenty-two cases of beaded hair—the congenital anomaly known as monilethrix—recorded lately in your columns by the McCall Anderson Memorial lecturer in dermatology in Glasgow,[1] is the family described in 1894 by the late Sir Thomas McCall Anderson himself, sixteen cases of the condition having then occurred in five generations, with a possibility of the condition having been present in a preceding generation as well. Between 1880–1 (when fourteen of these sixteen cases had been traced by the earlier observer and a chart pedigree obtained) and 1932 some fifty-two years have elapsed, a time sufficient to account for the appearance of a further two generations of persons in this stock from the South of Scotland. Moreover, one of the affected males in the earlier pedigree was aged 3½ years in 1880, while in the earlier of the two more completely worked out (final) generations in Dr. Goodwin Tomkinson's family tree the age of one of the affected males appears to be 55 years, exactly what it would be if he were the individual originally seen by McCall Anderson and surviving to the present time.

In your issue of December 3rd, 1932 (p. 1010), Dr. Tomkinson states that "solitary cases of monilethrix have been recorded," the impression being that his record of multiple cases is unique. McCall Anderson in 1894 claimed that no case had so far been recorded illustrative of its hereditary nature, and that his record was "so remarkable as an illustration of hereditary transmission of a very rare defect as to appear . . . well worthy of being put upon record." His record is more than that. It has been very generally overlooked by geneticists owing to being recorded in the second edition (1894) of his *Treatise on Diseases of the Skin* (pp. 59–61), but this record assumes added importance as one of the earliest published pedigrees showing the occurrence of Mendelian inheritance in man. W. C. Farabee's pedigree of brachydactyly, published in America in 1905, has been said to be "the first Mendelian case to be demonstrated in man,"[2] a similar human condition being recorded by H. Drinkwater three years later in this country; but McCall Anderson's pedigree was published in 1894, six years before the re-discovery of Mendelism by Bateson, Correns, and de Vries. The matter is of sufficient importance to warrant republication of his pedigree, redrawn with modern conventional symbolism, and supplemented by details furnished in the text (eleven further individuals added by 1888, two affected, nine unaffected; original pedigree compiled in 1881):



From this it will be seen that the condition had occurred in sixteen individuals in at least five generations, affected persons transmitting to 41.2 per cent. of their children—that is, out of thirty-four children of affected persons fourteen had themselves been affected. By theory this number should have been seventeen. An unaffected son of an affected parent himself had unaffected children.

In Tomkinson's pedigree, excluding three children who died in infancy and whose exact condition must be doubtful, in the last two generations nineteen out of thirty-six children of affected persons themselves showed the condition, a percentage of 52.8, which corresponds to the theoretical requirements for inheritance of a Mendelian dominant. If these two Scottish pedigrees, separated by the time required for the birth of two further generations, do not represent the same family, there is a strong suggestion that they represent families genealogically as well as geographically connected, owing descent to a common ancestor (or ancestress) affected in the manner in question. As Tomkinson himself notes, citing O'Donovan to the effect that J. Schutz had only seen one case in seventeen years in Frankfort, the condition is one of extreme rarity; the independent occurrence in a restricted geographical area of two such identically affected families, each showing the same mode of inheritance, passes the bounds of easy credibility.

The problem of the aetiology of this condition remains to be solved. McCall Anderson quoted W. G. Smith[3] to the effect that "it represents a curious freak of perverted nutrition, there being, so to speak, a regular succession of periods of growth and of atrophy, or a periodic alternation of activity and sluggishness." Tomkinson, by means of a biopsy, traced the condition to an intrafollicular cause. It is possible that some light may be thrown on its mechanism of causation by a study of a comparable condition in other animals, for it would seem that this condition—disease when it occurs in man—is the normal state of the hair of the shrews, a family (Soricidae) of small insectivorous mammals, of which some three different species occur in Britain. That these creatures have hair of this distinctive type, showing alternate broader and narrower zones, is not alluded to in two recent (1931) works devoting considerable space to consideration of the hair characters of different species of animals. It is not improbable, too, that such a rhythmic character impressed on living or semi-living structures may be allied to the Liesegang phenomena, which depend

[1] Tomkinson, J. G.: *British Medical Journal*, December 3rd, 1932, p. 1009.

[2] Bateson, W.: *Mendel's Principles of Heredity*, 1909, p. 210.

[3] Smith, W. G.: *British Medical Journal*, 1880, i, 636.

for their origin on the physico-chemical nature of colloidal matter in its reaction to the diffusion through it of solutions of electrolytes, or, in certain cases, to the liberation within it of such substances. From this point of view there may be a definite relationship between the mechanism of causation of this condition and that of the pigmentary or gaseous deposits in banded or striated hairs and feathers, which are of much more common occurrence in nature.

The microscopical appearance in Tomkinson's article of a single hair may be compared with the illustration given by McCall Anderson (Fig. 7, p. 59) of six hairs from five affected persons in the family group he recorded. —I am, etc.,

Manchester, Dec. 20th, 1932. W. J. RUTHERFURD.

Mastoid Drainage

SIR,—I should have thought that in the experience of most aural surgeons the drainage of the mastoid was rather too long delayed instead of being premature, as suggested by Mr. Douglas Crow in his note in your issue of December 17th, 1932 (p. 1104). I hope this note will not lead to practitioners postponing sending their cases for investigation and operation at an early date.

I have consistently urged that an earlier mastoid operation is indicated, and although one realizes quite clearly Mr. Crow's point, yet I should have thought that most aural surgeons would never have considered operation at the stage to which he objects. Broadly speaking, I think it is necessary to impress upon practitioners that large numbers of cases of mastoid involvement are treated as though the disease were confined to the middle ear; in my personal experience I have never opened a mastoid antrum without finding a serious involvement of the structures, and this may, I think, occur at an earlier date than is appreciated by Mr. Crow, as the fulminating type is by no means uncommon, especially when arising as a complication of influenza.—I am, etc.,

Bath, Dec. 22nd, 1932. H. NORMAN BARNETT, F.R.C.S.

Classification of Arthritis

SIR,—In trying to assess the value of any treatment for arthritis the chief difficulty is in the classification of the disease. There is a wide divergence of opinion as to when any particular type begins, when it ends, and when it merges into another type. Since it is generally accepted that a good *x*-ray negative is the best means of determining the actual condition of the joint, it should be possible to make clearly defined subdivisions according to the stage of the disease as follows:

Stage 1: Articular Arthritis.—The *x*-ray findings are negative or in favourable cases show cloudy inflammatory changes in the cartilage and the joint space.

Stage 2: Osteo-articular Arthritis.—The disease has also invaded the adjacent bone but the joint-space is still intact—that is, the joint is still a cartilage-bearing one.

Stage 3: Osteo-arthritis.—The joint-space is partially or completely obliterated and the joint is now a bone-to-bone-bearing one.

Stages 2 and 3 to be subdivided into "hypertrophic" and "atrophic" according to whether or not there is evidence of bone reaction with lipping, osteophytic overgrowths, etc.

The type of disease could be added as a prefix—rheumatoid, infective, or gouty. Without this prefix it would mean true osteo-arthritis, subdivided according to its stage into osteo-articular arthritis and osteo-arthritis.

A classification along these lines would give a definite clinical picture of the actual condition of the joint at the commencement of treatment, and would be especially valuable where the disease is limited to one or two large or an isolated group of small joints. In the polyarticular types, however, it might necessitate the placing of a patient in more than one stage. It would limit the word "cure" to Stages 1 and 2, and also exclude all cases of retrogression from Stage 2 to Stage 3. It would tend to promote earlier diagnosis by emphasizing the possibility of a cure or a marked improvement in the earlier stages. If adopted in various centres, collective information would soon be available and the results of any particular form of treatment more accurately assessed.—I am, etc.,

London, W.1, Dec. 21st, 1932. W. L. WATT.

The Medical Profession and the Lay Press

SIR,—Sir Harold Gillies (December 24th, 1932, p. 1166) raises an issue that requires solution, not only for the protection of the interests of the medical profession, but also in order to safeguard the public. The value of new methods of treatment can rarely be correctly estimated by the public, and editors of newspapers do not always appear to recognize fully their responsibility to the public for medical items in their columns. My work, for instance, has recently been referred to by a section of the lay press (it is hardly necessary to say, without my personal knowledge) in a way that is grossly inaccurate. It has been implied that I have discovered new methods of treatment, and from letters I have received it is clear that one effect of this has been to arouse false hopes in the minds of friends and relations of patients who are incurable. Even if the lay press has little concern in causing embarrassment to members of the medical profession and to their work, surely it would wish that its information to the public on medical matters should not give rise through its inaccuracy to unnecessary mental suffering.—I am, etc.,

London, Dec. 24th, 1932. HUGH CAIRNS.

British and Foreign Spas

SIR,—Dr. Geoffrey Holmes, in his letter which you published on December 17th, 1932, very successfully refutes a statement made by a medical correspondent in a newspaper that British spas compared with German spas do little for poor patients. He mentions the hospitals at Bath, Buxton, and Harrogate. It is of general interest to add that at Droitwich there are two hospitals, a clinic, a convalescent home, and a hostel, with some two hundred and fifty beds, available for the same class. —I am, etc.,

Droitwich, Dec. 28th, 1932. A. R. NELIGAN.

Coroners and Evidence

SIR,—It is true that eminent judges have said that the coroner is not fettered by the strict rules of evidence which prevail in ordinary common law courts. On the other hand, if the coroner had at his elbow a voice which first softly murmured, "You can't ask that," and then, rather louder, "That's not evidence; don't answer," and, finally, if a robed figure stood up beside him and remarked, in a tone of pity rather than contempt, "My friend knows he can't ask that," we might hear less nonsense in the coroner's court. Counsel who persist after such interruptions may receive some such rebuke as this: "Mr. Jones, if what you say is right, I have yet to learn my business, after forty years in the law."

During the twelve years I was at the Common Law bar I came to see that examination-in-chief required even greater skill than cross-examination; that able advocates often reduced their cross-examinations to very few questions, turned to the jury with a smile, and sat down.

Old Bailey counsel have a maxim, "Never cross-examine a detective." As a rule, only very white wigs try to heckle medical men. One often wonders how many, or how few, coroners have ever worn robes at all.—I am, etc.,

GEORGE JONES, M.B.
London, S.E., Dec. 29th, 1932. Barrister-at-Law.

Psychology in the Curriculum

SIR,—There can be no doubt that the insertion of psychology in the medical curriculum as a subject to be studied simultaneously with anatomy and physiology (which Mr. Bourne suggests) is a reform badly needed and long overdue. This was a recommendation put forward by a subcommittee of Section J (Psychology) of the British Association, of which I was chairman, five years ago, and its need becomes more obvious every year.

Dr. McBride raises the old cry that psychology cannot be called a science, and that it consists of "various forms resting upon hypotheses rather than upon reliable data." Actually it suffers from a plethora of accurately ascertained facts, and from a poverty of well-grounded hypotheses. But the latter defect is being gradually made good in the clash and conflict of pretentious and one-sided views. We must look, not to the voluble adherents of special "schools," but to the well-trained scientists, who represent psychology in the universities throughout the world, for an ever-developing and ever more consistent presentation of the subject.

The various trends of thought and research in modern psychology are not mutually exclusive (except in the popular mind)—they are mutually supplementary. As health and disease are matters of adaptation and adjustment of the whole man—mind as well as body—psychological knowledge is an essential part, and no small part either, of medical theory and practice.—I am, etc.,

London, W.1, Jan 3rd. WILLIAM BROWN.

Members of the Royal College of Surgeons

SIR,—Every possible moderate and reasonable argument has been put forward for the case of representation of Members of the Royal College of Surgeons of England upon its council, not once alone, but times innumerable. It would be mere waste of time to repeat our logical statements, which have never been met and often pointedly evaded. It seems wiser to review the present position from a different, though none the less emphatic, aspect, and for this I would choose to give a story of its history in legend form.

There was once a mediaeval town, in the midst of which stood an old castle surrounded by a moat. The castle was guarded by a governor and twenty-four knights. The population of the town was about 18,000, but more accurately nearly twice that number if the full extent of its jurisdiction was taken into account. The citizens looked to the governor of the castle for protection *and justice, which was not unnatural.* By a custom, born of time and mutual necessity, one day a year was set apart for a delegation of the citizens to be received by the governor, in order that reforms for the benefit of the inhabitants might be suggested. When this day arrived the drawbridge was dropped, and the delegates marched over the moat to be received in the castle by the governor and as many of the twenty-four knights as appeared to be interested in the proceeding.

The governor received the delegates with marked courtesy and cordiality, listened attentively to their petition, and then informed them that the matter would have his careful consideration and that an answer would be given in due course. The delegates were then entertained with light refreshment. After this they tramped once more across the moat, and the drawbridge was hoisted, only to be let down again, so far as they were concerned, in a year's time. Now this procedure happened every year for some forty-five years, till things began to pall, and it suddenly dawned upon the inhabitants that, like the yokel in the country fair, they had been pitifully hoodwinked.

Annually, for the good of the town, they had requested the governor's permission for two of their number to be brought into closer contact with the castle; annually this request had been denied, but no reason given. Why was this answer not forthcoming? The real cause then became evident to the citizens—the ethical reasons put forward were of so strong and so just a nature that they were unanswerable.

We are too proud to go down on our bended knees to supplicate the Council to give us that which is our due; but we can and do appeal to them, at this time of the year, when "peace on earth to men of good will" prevails. If the Council can but ascend above those mists which dim the vision of the future into the clarified atmosphere of enlightened thought, they will remove that single stigma under which the Royal College of Surgeons now exists, and, by recognizing the practical need for co-operation with its members in the great march of progress, it will increase the value and dignity of our beloved College.—I am, etc.,

Crouch End, N.8, December, 1932. T. WILSON PARRY.

Obituary

SIR ALEXANDER HENDRY, K.C.V.O., M.D.

Late Surgeon Apothecary to His Majesty's Household at Balmoral

We have to announce with regret the death on December 29th, 1932, at Aberdeen, of Sir Alexander Hendry, who for many years had been one of the best-known and most popular practitioners in West Aberdeenshire. He was born at Aberdeen in 1867, and after being educated at Aberdeen Grammar School studied medicine at the University of Edinburgh, where he graduated M.B., C.M. in 1892, proceeding to the M.D. in 1901. Taking up general practice soon afterwards at Ballater, he quickly attracted a large practice among the local populace and the visitors who frequent Upper Deeside in the summer months. He also took a great interest in local affairs, was a justice of the peace for Aberdeenshire, and was elected provost of the town of Ballater a year ago. During the war he did good work as medical officer in charge of the Victoria Auxiliary Hospital at Ballater.

Sir Alexander Hendry had a long and close connexion with the Royal household at Balmoral, which is situated some seven miles from Ballater. Here he was appointed medical attendant on the staff in 1904, and six years later he was appointed surgeon apothecary to His Majesty's Household, a post which he retained until last year. For his services in this connexion he was created M.V.O. in 1911, C.V.O. in 1924, and had the distinction of K.C.V.O. conferred upon him in 1931 by the King while the Court was in residence at Balmoral. He retired from practice last year owing to ill-health.

OSCAR BAGSTER TRUMPER, M.B., B.CH.

F.R.C.S.ED.

We regret to record the death, on December 26th, 1932, of Dr. Oscar B. Trumper of Aston Manor, Birmingham, after an illness of twelve days. He was born in 1872, and received his education at Yorkshire College, Leeds, graduating M.B., Ch.B.Vict., with honours, in 1894, and M.B., Ch.B.Leeds in 1906; in 1904 he obtained the F.R.C.S.Ed. After holding resident appointments at the Leeds General Infirmary, Dr. Trumper practised at Wakefield, Market Rasen (Lincs), and held the office of medical officer of health to the urban district council. In 1909 he removed to Birmingham, where he practised until his

death. A member of the Panel Committee, and also a part-time regional medical officer under the Ministry of Health, Dr. Trumper took great interest in the work of the British Medical Association. He was chairman of the Birmingham Central Division in 1923–4, president of the Birmingham Branch in 1930–1, and a member of the Representative Body in 1919; at the time of his death he was a member of the Executive Committee of the Birmingham Central Division. He is survived by his widow, one daughter, and one son, who is a member of the medical profession.

A colleague writes: For many years Trumper held a leading position in Aston, both as a medical man and as a citizen. He had excellent business abilities, and took an active part in all things that concerned the medical profession. Indeed, no committee was complete without Trumper. The manifold duties of his many offices were discharged with dignity, zeal, and ability. He spoke with ease and fluency, and his wise counsel will be missed by his colleagues. Outside medicine he was a versatile and cultured man. He kept abreast of the recent discoveries in science, and particularly astronomical science, and was widely read in general literature and in archaeology. There was, I believe, no greater authority on Aston Parish Church than Trumper, who knew the history of every monument and the date of every moulding as only an expert can. For a series of years he was warden of the fine old church which he loved so well, and for which he had worked so hard. Trumper had a fine presence and a genial disposition; he was devoid of affectation or pretence, and his sympathy and help were freely given to all who sought them. His keen sense of humour, his well-stored mind, and his conversational powers made him a delightful companion alike in the home and in the world of men. A few years ago he acquired a plot of land adjoining Clifford Castle on the Wye. He excavated the ruins, mapped out a plan of the original building, and designed for himself a house which is so constructed that each window gives the best available view of the valley of the Wye. It was here, under the shadow of the ruined tower, and overlooking a magnificent expanse of country, that Trumper hoped to spend the leisure time of his declining years. But Trumper is gone: his death is a sudden and severe loss to the medical profession and to the community with which he worked.

Dr. THOMAS DAVIDSON died at Los Angeles on November 28th, 1932, at the age of 75. He was a distinguished fellow student with the late Dr. Freeland Fergus at Glasgow University, where he graduated M.B., C.M. in 1880, and proceeded to the M.D. in 1887. After a few months as locumtenent for Dr. Sewell, late of Helensburgh, he went to Thornhill, Dumfriesshire, as assistant to Dr. Hoggan, and on the retirement of the principal succeeded to the practice. Owing to the heavy day and night work inseparable from a large country practice his health broke down. In 1889 he sought a milder climate, and settled with his brother, Dr. Anstruther Davidson, at Los Angeles, at that time an almost unknown city, where they built up a practice. Though he had subsequently to retire from active work through ill-health he still kept abreast with the advancement of medicine, and retained his membership of the British Medical Association. He took great interest in the growing of oranges, and was one of the first pioneers of Hollywood, where he owned an orchard.

The following well-known foreign medical men have recently died: Dr. ASTLEY PASTON COOPER ASHHURST, professor of clinical surgery at the Pennsylvania School of Medicine, Philadelphia, and author of *Surgery, its Principles and Practice*, aged 56; Dr. SIDNEY YANKAUER, a prominent New York laryngologist, aged 60; Geh. Med. Rat. Professor HERMANN KÜTTNER, director of the university surgical clinic at Breslau, aged 62; Dr. A. CHAUFFARD, honorary professor in the Paris Faculty of Medicine, member of the Académie de Médicine, and Commander of the Legion of Honour; Dr. E. FLATAU, a Polish neurologist; and Dr. GUILLERMO MARQUEZ, professor of children's diseases at the Bogota faculty of medicine.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

THIRD M.B.—(*Part I, Surgery, Midwifery, and Gynaecology*): J. C. G. Anderton, E. F. Baines, H. Barcroft, G. F. Barran, C. G. Batty-Smith, W. T. C. Berry, C. E. Bevan, E. V. Bevan, R. W. Billington, G. O. Brooks, R. H. Brown, J. R. Chambers, A. H. Charles, F. H. Coleman, J. Collinson, P. T. Cooper, A. G. Cross, H. S. Davis, L. W. B. Dobbin, J. R. Duffield, W. G. Evans, A. A. G. Flemming, P. H. R. Ghey, P. R. Goodfellow, R. W. Graham-Campbell, S. J. Hadfield, B. P. Harris, F. G. Hinks, M. I. A. Hunter, T. B. Jones, A. H. Knowles, D. Kyle, R. C. Langford, C. A. Lewis, W. Lewis, T. E. S. Lloyd, M. W. Lloyd Owen, K. Lumsden, F. D. MacCarthy, A. B. MacGregor, W. S. McKenzie, F. G. Maitland, T. C. Maling, G. J. H. Maud, J. W. Maycock, M. P. Morel, C. W. Morley, H. J. V. Morton, T. P. Mulcahy, J. P. S. Peck, K. M. A. Perry, F. W. J. Platts, J. S. M. Pringle, S. A. Propert, P. J. Richards, W. F. Richards, F. Ridehalgh, I. G. Robin, K. Robson, G. Scott, E. P. Sharpey-Schafer, D. W. Smithers, J. G. C. Spencer, T. V. Tattersall, E. W. Taylor, H. B. Tipler, G. E. H. Tisdall, G. I. Watson, W. E. Wells, C. J. G. White, A. Willcox, J. Wilson, R. M. Yeo. *Women*: D. K. Emery, A. C. Taylor. (*Part II, Principles and Practice of Physic, Pathology, and Pharmacology*): S. E. Birdsall, C. P. F. Boulden, A. Bowen-Davies, E. Bradbury, W. D. Brown, J. W. Campbell, C. A. Clarke, F. J. Curtis, S. F. L. Dahne, W. D. Dick, L. W. B. Dobbin, R. H. Dobbs, G. A. Emmerson, R. H. Foster, D. W. C. Gawne, W. G. Gill, G. W. Hall-Smith, E. R. Hargreaves, B. P. Harris, J. Howell, N. M. James, H. V. Knight, A. R. R. Le Fleming, R. S. Lewis, G. A. Mandow, A. R. R. Mears, D. A. Metcalf, G. A. Miller, F. H. Morrell, J. Parkes, E. B. Pawson, R. V. Payne, K. M. M. Dobbs, J. C. Drury, C. A. Grove.

UNIVERSITY OF LONDON

Lectures

A course of six lectures on factors in nutrition will be given by Professor S. J. Cowell at Bedford College, Regent's Park, N.W., on Wednesdays, January 11th, 18th, 25th, and February 1st, 8th, and 15th, at 5 p.m. Four lectures on the integration of the circulation will be delivered at King's College, Strand, by Professor R. J. S. McDowall on *Thursdays*, January 12th, 19th, 26th, and February 2nd, at 5 p.m. Dr. L. E. Bayliss will give four lectures on the respiratory functions of the blood at University College, Gower Street, W.C., on January 16th, 20th, 23rd, and 27th, at 5 p.m. Two lectures on reflex action will be given by Sir Charles Sherrington at University College, Gower Street, W.C., on Mondays, January 30th and February 6th, at 5 p.m. Professor Max Bergmann (Dresden) will deliver three lectures on the chemistry of proteins at University College Hospital Medical School on January 20th, 23rd, and 25th, at 5.15 p.m. Admission to all the above lectures is free without tickets.

The following candidates have been approved at the examination indicated:

M.S.—*Branch I* (*Surgery*): O. V. Lloyd-Davies, E. G. Muir (University Medal).

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated.

Surgery.—J. L. Bates, A. E. Glanvill, J. Harris, C. A. Saggoo, L. Wailer.

Medicine.—W. E. P. Corbett, F. M. F. Forrest, M. F. Levick, E. M. F. O'Donovan, J. C. Selnes.

Forensic Medicine.—M. F. Levick, C. W. O'Donoghue, J. C. Selnes, M. Sourasky, E. Teplitzky.

Midwifery.—L. Bhanot, P. D. Bhatt, E. L. Burgess, W. H. Ekin, A. J. McGuire, J. C. Selnes, T. B. Smith.

The diploma of the Society has been granted to Messrs. J. L. Bates, P. D. Bhatt, F. M. F. Forrest, J. Harris, M. F. Levick, C. A. Saggoo, J. C. Selnes, and E. Teplitzky.

Medical News

The nineteenth annual conference of the National Association for the Prevention of Tuberculosis will be held on July 13th, 14th, and 15th in Cardiff, by invitation of the City Council. Particulars will be issued in due course.

The annual general meeting of the Harveian Society of London will be held on Thursday next, January 12th, at 11, Chandos Street, W., at 8.30 p.m., when the president will give his address on the role of specialization, followed by a smoking concert.

At the next meeting of the Pharmaceutical Society of Great Britain, to be held at 17, Bloomsbury Square, W.C., on Tuesday, January 10th, at 8.30 p.m., Dr. G. Roche Lynch, senior official analyst to the Home Office, will deliver a lecture on poisons and their effects. Members of the society are invited to bring friends. Refreshments will be served after the meeting.

A course of twelve illustrated lectures on primitive man by Dr. T. M. Finlay began on January 4th in the lecture theatre of the Imperial College of Science, Exhibition Road, South Kensington. The lectures will be continued on Mondays, Wednesdays, and Fridays, at 5.30 p.m., until January 30th. Admission is free.

Factory cleanliness in the food industry will be the subject of a discussion arranged jointly by the Royal Sanitary Institute and the Food Group of the Society of Chemical Industry, at 90, Buckingham Palace Road, S.W., on Friday, January 20th, at 5.30 p.m. The discussion will be opened by Mr. E. B. Hughes, M.Sc., who will be followed by Dr. Thomas Carnwath (Ministry of Health), Dr. Gerald Leighton (Department of Health for Scotland), Dr. Charles Porter, Sir Weldon Dalrymple-Champneys, and Dr. T. W. Naylor Barlow.

Twenty lectures, open to the medical profession only, on psychological types and mechanisms, being an introductory course in psychological medicine for the general practitioner, will be given at the new premises of the Institute of Medical Psychology (formerly the Tavistock Square Clinic) at Torrington Place, W.C.1, on Wednesdays, beginning January 18th. Dr. E. Graham Howe will lecture each day from 3 to 4 o'clock, and Dr. H. Crichton-Miller from 4.30 to 5.30. The fee for either series is £1 11s. 6d., and for both series £2 2s. Tickets must be obtained in advance from the honorary lecture secretary; cheques payable to the Institute of Medical Psychology. A lecture on occupational therapy, and a demonstration of the methods by which such treatment can be scientifically applied to physical and mental illness, will be given on Saturday, February 4th, at 3 p.m., by Miss Joan West. Tickets (price 2s. 6d.) to be obtained in advance from the lecture secretary.

A course of lectures on rheumatism and arthritis as a public health problem will be delivered at the Royal Institute of Public Health, 23, Queen Square, W.C., on Wednesdays at 4.30 p.m. The inaugural lecture will be given by Professor W. Langdon Brown on Wednesday, January 18th; Dr. R. Fortescue Fox will lecture on rheumatism as a social and industrial problem on January 25th; Dr. C. W. Buckley on the economics of rheumatism on February 1st; Dr. W. S. C. Copeman on a scheme for industrial rheumatism on February 8th, and Miss M. W. Edminson on the rheumatism clinic and its relation to the social services, on February 15th. A demonstration will be given at the British Red Cross Society's Clinic for Rheumatic Diseases, Peto Place, N.W., on February 22nd, at 11.30 a.m. The demonstration is restricted to fellows, members, and students of the institute, but others may attend the lectures, for which no ticket is required.

The following international medical post-graduate courses will be held in Berlin in the spring: internal medicine, from February 27th to March 4th; practical haematology, from March 6th to 11th; indications for, and the technique of, modern diagnostic and therapeutic methods, from March 10th to 16th; dermatological and venereal diseases, from March 20th to April 1st; practical advances in radiotherapy, April 2nd to 9th; and surgery, from April 24th to 29th. In the autumn there will be courses in endocrinology, diseases of old age, thoracic surgery, anaesthetics and analgesics, colloid therapy, diseases of children, ophthalmology, and orthopaedics. Further information can be obtained from the Information Bureau of International Courses, Kaiserin Friedrich Haus, Robert Koch Platz 7, Berlin, N.W.7.

The Fellowship of Medicine and Post-Graduate Medical Association announces a demonstration of cases of general medical and surgical interest at the Lambeth Hospital on January 13th, at 2 p.m. A series of lectures on "Practical problems in medicine and surgery" will be given at the Medical Society of London, 11, Chandos Street, W., on Tuesdays at 4 p.m., beginning on January 17th. A demonstration of *x*-ray films, especially suitable for M.R.C.P. candidates, will be given by Dr. P. Kerley at the Medical Society of London on Friday, January 20th, at 4.30 p.m. A whole-day course in cardiology will be given at the National Heart Hospital from January 16th to 27th. It is hoped to arrange a practical demonstration of cases illustrating diseases of children on January 26th at 8 p.m., at the National Temperance Hospital, Hampstead Road. Other forthcoming courses include dermatology, gynaecology, diseases of the chest, ante-natal treatment, etc. The above courses and demonstrations are open only to members and associates. Application for particulars should be made to the Fellowship of Medicine, 1, Wimpole Street, W.1.

The thirty-seventh Congress of French-speaking Alienists and Neurologists will be held at Rabat (Morocco) from April 5th to 12th, under the presidency of Professor Georges Guillain of Paris. The subjects for discussion will be psychotic encephalitis, the ataxias, and the medico-legal consequences of traumatic amnesia.

The German Society for Internal Medicine will hold its forty-fifth meeting from April 18th to 21st, 1933, in Wiesbaden, under the presidency of Professor Lichtwitz of Berlin. The subjects for discussion are: the significance of the heavy metals in physiology and pathology, and the pathology of the erythrocytes and haemoglobin. A survey of the problem of the suprarenal will probably be given on April 19th. Notice of papers, with manuscripts, must be sent not later than February 5th, 1933, to Professor Lichtwitz, Rudolf-Virchow Krankenhaus, Berlin.

A research fellowship has been founded at Nottingham University College with a view to developing physical methods for the diagnosis and cure of cancer, and Dr. L. A. Woodward has received the appointment. The local branch of the British Empire Cancer Campaign is contributing £500 for the purchase of instruments, and £100 annually towards the biochemical side of the work. A joint cancer research committee has been established including representatives of the University College, and Dr. F. H. Jacob, Mr. R. G. Hogarth, and Mr. A. M. Webber, representing the Notts branch of the campaign.

The sixtieth anniversary of the foundation of *Le Progrès Médical* by Désir-Magloire Bourneville was celebrated in Paris on November 23rd, 1932, by a dinner presided over by M. A. de Monzie, the Minister of Education.

Dr. Portmann, professor of oto-rhino-laryngology at Bordeaux, has recently been elected a member of the French Senate.

Messrs. John Bale, Sons and Danielsson, Ltd., announce for publication this month the seventh edition of *A Compendium of the Pharmacopoeias and Formularies*, by C. J. S. Thompson. It includes a synopsis of the new *British Pharmacopoeia, 1932*, as well as the official and unofficial formularies of the United States, the French Codex, and the last editions of the pharmacopoeias of ten other countries.

The publishing offices of Messrs. H. K. Lewis and Co., Ltd., have been moved from 28, Gower Place, to the new building. All communications should be addressed to 136, Gower Street, W.C.1. The telephone number is unchanged—Museum 2853.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Cracks on Nails

DR. CHARLES POLLARD (Worcester) writes: Can anyone suggest treatment or prevention for vertical cracks down the finger-nails, caused by the slightest of "hitches" in any article of clothing? The patient is somewhat "rheumaticky," but nothing definite, and otherwise enjoys good health.

Spasmodic Scapular Pain

"PERPLEXED" writes: I should feel grateful to have opinions on the diagnosis of the following case. A lady of 53 has had attacks of pain at the angle of the right scapula for the last two or three years. The pain is severe, and she describes it as a cramp or spasm, which lasts from ten seconds to half a minute. At the beginning there was an interval of two months between attacks. Lately she has had two or three in one day, and then the usual interval. She complains of chilly feelings very often by day and night, like cold water running down her back. She has dyspeptic symptoms at times, and nausea. Her teeth were x-rayed before onset of any symptoms, and some were thought to be septic, so they were all removed under an anaesthetic.

Fissure of the Lips

DR. EDMOND MURPHY (Cork) writes: If the fissures be filled with "durofix"—an adhesive sold in hardware shops—and renewed as required, the patient will soon be cured.

Softening the Beard

"A. T." (New South Wales) writes: There are three factors in "W. B. D.'s" problem (September 17th, 1932)—namely, the skin, the instrument, the operator. Warm water swells the capillaries and softens the papillae of the skin coincidentally with the softening of the beard. The razor slices the tops off these elevations, and the result is a multiplicity of small wounds—that is, a sore skin. Cold water contracts the capillaries and papillae, and gives a smooth surface to the razor, with a resultant minimum of injury. Safety razors are an abomination to all but those with silky beards. Of the "cut-throat" razors the old solid razor is infinitely better than the hollow-ground. The solid type was rediscovered in the war, and is coming into general use in Australia. The operator must learn the optimum angle to adjust between razor and skin, and this angle is much nearer 10 degrees than to the 60 degrees which appears to be habitual. Remembering the principle of the guillotine and other machines wherein a sliding cut is proved superior to any other, the shaver must learn to shave from heel to tip of the blade. The impossibility of adjusting this is the chief defect of the safety razor. Any soap which will give a free and tenacious lather is suitable. I have tried every powder, soap, and paste I have met, and find that few are better than others, but I recently found Elysium in a locally produced germicidal soap, "tenax"—a clear spirit soap, with an extract of native ti-tree (titrol), as a germicidal agent. My advice to "W. B. D." is to use cold water, a keen, solid blade held diagonally to the line of shaving, and at an angle of about 10 degrees to the skin; to eschew all preparations for after-treatment—unguents, powders, spirits, etc. If the face is at all raw at first rub in well a few drops of glycerin ʒij, ext. hamamel. ʒiij, ac. acet. glac. mx, aq. rosae ad ʒj. I have suffered agonies, as has "W. B. D.," and this is the essence of my experience. I would ask him to try it for three months and then to publish his findings.

Income Tax

Inspector's Inquiry re Purchase of House

"T. K." returned from abroad two years ago and started practice. The inspector of taxes has asked him from what resources he has bought a residence this year. Is he bound to supply information of this kind?

*** The inspector of taxes, as such, has no legal right to the information, but is presumably doing so in order that the responsible commissioners may have all relevant information before them when dealing with "T. K.'s" liability. We suppose that it would be sufficient to explain that the necessary capital was saved out of "T. K.'s" (non-taxable) earnings when abroad, especially if at the same time some indication is given of the approximate amount of those earnings, so that the inspector can see that the saving was practicable.

Sale of Practice—Expenses

"H. C. H." has recently sold his practice. Are the legal and agency expenses involved allowable for income-tax purposes?

*** No; the sale of the practice is a capital transaction, and the special expense is not deductible for income tax.

Medical Textbooks, etc.

"W. E. J." holds a hospital appointment, and inquires whether he can deduct from his salary (*a*) the expense of buying medical books, and (*b*) the cost of oil-immersion lens for microscope.

*** The expenses are allowable if necessarily incurred to carry out the duties of the office, and provided that the original cost is not claimed. For instance, if the hospital authorities require our correspondent to maintain an assortment of medical books for reference, etc., then the cost of maintaining the books up to date by the purchase of new editions would be admissible, but not the cost of the set of books originally provided.

LETTERS, NOTES, ETC.

Pain caused by Impacted Wisdom Teeth

MR. R. S. TAYLOR, M.R.C.S., L.D.S. (London, W.1) writes: I read with interest the memorandum by Dr. Graham Macphee in your issue of December 10th, 1932, on two cases of impacted wisdom teeth causing neuralgic pain. As Dr. Macphee points out, wisdom teeth are a more common cause of neuralgia than most people realize; in fact, nearly 50 per cent. of the wisdom teeth that are removed have given rise to neuralgic symptoms. Earache is a common association of impacted wisdom teeth, and I have seen one case of this nature that had been diagnosed as mastoid disease. A certain amount of doubt must be expressed as to the advisability of removing the second molar and leaving the wisdom tooth, as in the vast majority of cases the symptoms recur, which is not surprising, as it is possible to demonstrate the presence of micro-organisms in the pulps of nearly 50 per cent. of these wisdom teeth that have been removed.

Motor Car Licences

The Automobile Association emphasizes the fact that the fourteen days of grace only apply if the licence for a motor vehicle is taken out within that period. To renew the tax after "the days of grace" is insufficient, and may result in a prosecution. Another point often overlooked is that a vehicle used on any single occasion after the expiration of the old licence is immediately liable to duty. The penalty for such infringements is particular severe, the maximum fine being £20 or three times the value of the licence duty, whichever is the greater.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 46, 47, 49, and 50 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 48 and 49.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 7.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1 Herpes Zoster and Varicella

F. SALTZMAN (*Finska Läkaresällskapets Handlingar*, August, 1932, p. 653) correlates the incidence of herpes zoster and varicella in Helsingfors, where both diseases are notifiable (herpes zoster only since 1926). He publishes a table showing the incidence, month by month, of each of these diseases during the five-year period 1927–31, in which 1,826 cases of varicella and 782 cases of herpes zoster were notified. The monthly incidence of varicella showed, broadly speaking, the same curve from year to year, with a minimum of three cases or less in July and August, and a maximum of 45 to 142 cases in November, December, and January. Thus, in December, 1931, there were as many as 142 cases of varicella notified, whereas in July, 1930, there were only two such cases. The fluctuations were not so violent in the case of herpes zoster, which, however, usually showed a low level in the summer, with the fewest notifications in July, and a peak which reached its maximum in the winter, usually in January. The greatest discrepancy between the two diseases occurred in December, when the herpes zoster curve was relatively low. The author points out that a similar study was published in 1928 by Bókay, whose material was derived from Budapest in the period 1915–24. The parallelism of the two curves was less evident in his statistics than in the author's. Saltzman admits that his figures are too small, and the period he deals with too short, for far-reaching conclusions to be drawn from them. He notes that opposed to the doctrine of the identity of the two diseases is the clinical observation that varicella confers immunity to itself, and herpes zoster, as a rule, to itself. But cases have been observed of herpes zoster in persons who had previously suffered from varicella, and vice versa.

2 Administrative Problems of Diabetes

A. NORGAARD (*Nord. Med. Tidskrift*, September 3rd, 1932, p. 638) describes the administrative problems raised by diabetes among insured workers in Denmark, who, at the end of 1930, numbered 1,673,413. Only two generations ago diabetes was a rare disease in Denmark, and in 1890 only ten diabetics were treated in all the hospitals in Copenhagen. By 1924 this figure had risen to 608. In 1927 it was calculated that there were 4,247 diabetics in Denmark, and that some 900 of them were receiving insulin. This number has since risen considerably, and at the present time there are between 2,500 and 3,000 diabetics receiving insulin, while the total number of diabetics in Denmark is between 5,000 and 6,000. The sickness insurance organization, which came into being in October, 1921, plays a fourfold part in the lives of insured diabetics: (1) the prevention of threatened invalidism; (2) the treatment of patients already invalided; (3) the allocation of money; and (4) the maintenance by suitable measures of the residual working capacity of invalids in certain special cases. As this list of functions shows, the duties of this organization are far from being limited to the comparatively passive task of computing the working capacity of individuals and refusing or allotting pensions. It achieves much more than this: by keeping in touch with general practitioners, by putting the services of its specialists at their disposal, and by facilitating the provision of suitable remedies, it does much to ease the lot of the diabetic worker. How great is the part played by insulin is shown by the following. Before its introduction, 89 per cent. of insured diabetics applying for pensions were classified as permanent invalids—that is, as having a working capacity less than a third of the normal; in 1930 this percentage had been reduced to 38. Since 1928, 540 workers have applied for insulin instead of for pensions, and in most of these cases this request has been granted. By April 15th, 1932, only fourteen of these persons were known to have died, and it is unlikely that many, if any, deaths could have been overlooked. It will thus be seen that the expectation of life of the insured diabetic worker under present conditions in Denmark is relatively good.

3 Prophylaxis of Scarlet Fever

S. C. PEACOCK, M. WERNER, and C. COLWELL (*Amer. Journ. Dis. Child.*, September, 1932, p. 494), owing to an outbreak of eleven cases of scarlet fever in a children's hospital, performed the Dick test on 258 members of the staff, and took swabs from their noses and throats with the following results. In forty-five (17 per cent.) there were positive skin reactions, and seventy-two (28 per cent.) showed haemolytic streptococci in nose or throat. Of the forty-five Dick-positive individuals forty were inoculated with Dick toxin: of these, thirty-five (87.5 per cent.) were immunized to the point of negative skin reactions, thirty-two patients requiring five, and three needing six doses of toxin for immunization. Of the 186 adults with negative Dick reactions 70 per cent. gave no history of scarlet fever; 24 per cent. had had the disease; and in 6 per cent. the history was doubtful. No case of scarlet fever developed among the Dick-negative cases. Of the forty adults with positive Dick reactions, two contracted scarlet fever before the series of immunization was complete, and of the five individuals who were not immunized two had severe attacks of scarlet fever.

4 Recovery from Streptococcal Meningitis

E. LEWIS (*Arch. of Pediat.*, September, 1932, p. 632), who records an illustrative case, remarks that recoveries from streptococcal meningitis are being observed with increasing frequency, as is shown by the fact that Appelbaum has recently collected forty-six cases, including three of his own. Lewis's patient was a coloured girl, aged 8 years, who developed otogenic meningitis. Recovery followed repeated lumbar puncture, transfusion of citrated blood, and removal of the focus of infection by mastoidectomy.

Surgery

5 Carcinoma of the Prostate

J. R. CAULK and S. B. BOON-ITT (*Amer. Journ. Cancer*, September, 1932, p. 1024) compares carcinoma of the prostate with that form of the disease which occurs in the female breast. Both are diseases of the latter part of middle life, and spread very early by way of the lymphatic system; they are also alike in their power to disseminate and in their predilection to skeletal metastasis. In neither of the two types of carcinoma is the prognosis good, and the end-results of treatment are still unsatisfactory. Carcinoma of the prostate is not uncommon, and it is suggested that chronic prostatitis may be responsible for a definite number of cases. Emphasis is laid on the need for early and careful attention to be paid to all inflammatory lesions of the prostate. Diagnosis of carcinoma of the prostate in the 107 cases under review was made through the process of exclusion, supported by the characteristic feel of the carcinomatous gland on palpation per rectum, and confirmed by microscopical examination of tissue obtained by the punch operation or by prostatectomy. It is a disease of late middle age, nearly 94 per cent. of patients being over the age of 50. Symptoms of obstruction, ranging from some difficulty in voiding to complete retention of urine, and frequency of urination are the two most common complaints in the early stage of the disease. Pain in the lower part of the

back and legs may occur, and is suggestive of extension of the growth or metastatic processes. Extension of the carcinomatous process by way of the seminal vesicles appears to predominate, with spread to the pelvic bones ranking next. Metastases in the skull and other bones are also common. The cautery punch operation, in conjunction with radium and *x*-ray therapy, relieves the obstruction, and retards the progress of the disease. In the series of cases under review 72 per cent. so treated gained complete relief from obstruction, while 29 per cent. of the patients lived over three years and 10 per cent. over five years. The operative mortality was only 2.5 per cent., as compared with 17 per cent. following prostatectomy.

6 Tuberculosis of the Large Intestine

Two types of intestinal tuberculosis occur—the hyperplastic (tuberculoma), and ulcerative colitis. The latter is frequently so extensive that an operation is inadvisable or impossible. The former lesion, generally seen in the caecum and frequently involving the terminal ileum, can be successfully removed. F. W. RANKIN and S. G. MAJOR (*Surg., Gynecol. and Obstet.*, October, 1932, p. 494) present a report of sixty-five cases observed at the Mayo Clinic, in which short-circuiting operations or bowel resection, or both, were performed. The bovine type of *B. tuberculosis* is more frequently the cause of primary intestinal lesions than the human type. The incidence of hyperplastic intestinal tuberculosis is greater than has been recognized; it is more prevalent among males than females, and the ileo-caecal region is the site most frequently involved. Pain and loss of weight are the most constant symptoms. Diarrhoea occurs in many cases; it may alternate with constipation. Intestinal *haemorrhage* is rare. In a certain percentage of cases no extra-intestinal tuberculous focus can be found. Radiological examination is of diagnostic value. Radical extirpation of the ileo-caecal coil with end-to-side anastomosis between the terminal ileum and transverse colon in one (preferably) or two stages is the procedure of choice. If short-circuiting is necessary, ileocolostomy or ileosigmoidostomy may be performed, or, if the lesion is limited to the small intestine, entero-enterostomy or ileocaecostomy. The present cases show that results from resection are definitely better than from anastomosis alone. The chief complication is a gradual and insidious onset of obstruction, and a faecal fistula is also not uncommon; these two conditions should be treated surgically. Perforation and intestinal haemorrhage are more common in tuberculous enterocolitis than in hyperplastic tuberculosis. Surgical measures should always be supplemented by careful medical supervision.

7 Treatment of Congenital Torticollis

H. L. ROCHER (*Bordeaux Chir.*, October, 1932, p. 424) describes the various methods of treatment which have been used for congenital torticollis. These include forcible correction under an anaesthetic, open operation, and tenotomy of the sterno-mastoid muscle, complete or partial excision of the muscle, and finally subcutaneous tenotomy. Rocher prefers to operate before the age of 2 in the case of a child; under general anaesthesia he performs a subcutaneous tenotomy of the muscle at its insertion into the sternum. The clavicular head is then divided either through the same or a second incision. Great care is necessary to avoid causing injury to the important structures at the base of the neck. Venous haemorrhage often follows the operation, but is usually easily controlled by pressure. The author emphasizes the importance of the division of both attachments of the muscle, and of the forcible rupture of the deep fascia by the movement of over-correction of the head position, or, in older cases, by pressure of the fingers. A firm dressing is then applied over the small incisions, with a collar to hold the head in the over-corrected position. This collar is worn by the patient for about six weeks after the operation; at the end of this time massage is carried out, the collar being worn for about three months altogether. Since 1914 about sixty cases have been treated in this way with excellent results, only two complications having arisen. In one instance venous haemorrhage followed subcutaneous tenotomy, and in the other an over-correction caused a torticollis on the opposite side. It has been found that this method of treatment gives the best aesthetic results in the shortest time and with the minimum of operative risk.

Therapeutics

8 Injection of Liver Extract in Pernicious Anaemia

H. M. CONNER (*Journ. Amer. Med. Assoc.*, August 20th, 1932, p. 614) administered liver extract by injection to thirty patients with pernicious anaemia, twenty-seven of whom were studied in hospital. The intramuscular route was used in twenty-one instances, the dose being 2 to 6 c.cm. of an extract of which 2 c.cm. was the equivalent of 10 grams of liver. Three patients received intravenous injections, the dose being 20 c.cm. of an extract derived from 100 grams of liver. Three other patients were treated by intramuscular injections of an extract of which 3 c.cm. represented 100 grams of liver. In the case of the remaining three patients the degree of observation was regarded as insufficient to justify the results obtained being reported yet. Conner is satisfied that the extract from a very small amount of liver produced maximal results when administered by injection. The effects on the reticulocytes, red cells, haemoglobin, and other blood elements, as well as on the general symptoms, were similar to but more rapid than those following oral administration. The value of the treatment as regards the neurological symptoms could not be definitely ascertained, but the author does not think that there was any evidence to suggest that the poor results usually following oral therapy were improved on by injection treatment. Untoward symptoms, except pain, did not occur in cases in which intramuscular injections of the less concentrated extract were given daily. Chills were noted in two instances, and pyrexia in three, in which the intravenous route was used. There was no reaction definitely attributable to the intramuscular injection of the more concentrated extract, but in one instance status epilepticus occurred after the second injection in a case of epilepsy and syphilis of the central nervous system. Conner agrees that no patient should be treated by injection if the oral method is applicable, but there are some contingencies in which injection therapy is definitely indicated—for example, in the case of patients who are acutely ill, who have an extreme degree of anorexia, who are vomiting repeatedly, who particularly dislike liver and the other effective substitutes, or who manifest symptoms of gout after the oral administration.

9 Treatment of Syphilis in Denmark

E. EHLERS (*Ugeskrift for Laeger*, September 15th, 1932, p. 897) describes his routine and experiences with the treatment of syphilis in the Communal Hospital in Copenhagen. The dose of neosalvarsan with which he begins a course of six or seven injections is 45 cg. This dosage is increased to 60 and then to 75 cg., which is now his maximum. Should the first injections of neosalvarsan be followed by definite symptoms of poisoning, they are discontinued and only bismuth is given. Bismuth hydroxide is not employed, preference being given to "vijochin" (Leo), which is an iodine-quinine preparation of bismuth. As a rule fifteen injections of bismuth complete one course—30 cg. twice a week. The injections of neosalvarsan are started after two injections of bismuth have been made. In the case of children preference is given to a soluble preparation of bismuth (Quinby lipo-soluble), which is easily administered by subcutaneous or intramuscular injections. Since introducing bismuth Professor Ehlers has entirely discarded mercury, and he regards potassium iodide merely as a useless and troublesome relic of the past. When a patient has begun treatment in the early sero-negative stage, two courses

of injections will suffice, but he must continue under Wassermann tests. On the other hand, early cases of syphilis which begin with headaches are assumed to be complicated by syphilitic basal meningitis, and are not released from hospital with less than three months' treatment. This rule is followed even when the examination of the cerebro-spinal fluid is negative. The nature of the further treatment of such cases is determined by the Wassermann reactions, which are repeated regularly every month. Ehlers quotes figures in support of his opinion that syphilis is about to disappear. At the beginning of this century Copenhagen, with a population of 700,000, had some 2,800 new cases of syphilis every year—about fifty-five every week. At the present time some weeks may pass without a single new case, and the maximum is five or six new cases a week.

10 Treatment of Herpes Zoster

E. LENGLET (*Bull. Soc. de Thér.*, October 12th, 1932, p. 176) during the last twenty years has ordered the following treatment for cases of herpes zoster with good results. The patient is given a cachet containing 5 cg. of quinine sulphate and 7 cg. of sodium salicylate every hour, ten times daily, for five days. The earlier the treatment is adopted, the more likely it is to be successful, but it is still efficacious if first employed when the herpes is at its height. No bad effects have been observed.

Dermatology

11 Leucoderma

H. C. L. LINDSAY (*California and Western Med.*, July, 1932, p. 36) uses vitiligo and leucoderma as synonymous terms, and suggests that there may be an endocrine origin for this condition of depigmentation of the skin. He discusses the various forms of empirical therapy that have been employed in this intractable condition, and recommends intravenous injections of gold sodium thiosulphate in cases where photo-sensitivity appears to be concerned. Toxic reactions, in Lindsay's opinion, can be avoided by employing small doses at first, and not exceeding a total of twenty injections. Among the conditions which cause leucoderma, or are associated with it, are hyperthyroidism, Addison's disease, pregnancy, syphilitic involvement of the sympathetic nervous system, chronic intestinal infections, tuberculosis, and leprosy. Lindsay deduces that this skin depigmentation originates from disturbances which affect some part of the nervous system, and/or the chemistry of the tissues in its relation to the rays of the sun or to some other external factor. He believes that the injection of gold sodium thiosulphate brings about repigmentation of the leucodermic areas, with a relative lessening of pigmentation in the hyperpigmented areas—in other words, an "averaging" of the pigmentation. Recurrence may ensue, but not invariably. Such gold therapy in the author's experience was most effective in patients who had symptoms of mild hyperthyroidism; it might also be expected to be useful in cases associated with tuberculosis or syphilis.

12 Brucella Dermatitis

Brucella melitensis of the *abortus* type occasionally produces a dermatitis, and L. F. WEBER (*Arch. Derm. and Syph.*, September, 1932, p. 422) records a case of this occurring in a veterinary surgeon. The eruption was confined to the left forearm and right arm, was most acute on the flexor surfaces of the latter, and simulated the severe dermatitis due to an external irritant on a skin highly sensitized to antiseptics. For various reasons, antiseptics could be eliminated as possible causes. The dermatitis was always contracted in the spring and autumn—the periods of prevalence of contagious abortion in cattle—and only appeared during attendance on aborting animals. Haxthausen and Thomsen have shown that cultures of the pus from infected abortion material are negative, and therefore they believe that the dermatitis is not due to direct bacterial infection. Weber's patient had no constitutional symptoms of undulant fever, and Haxthausen suggests that the dermatitis from *Brucella melitensis* (*abortus* type) is an allergic reaction due to sensitization to the antigen, which had resulted from repeated successive exposures to the organism. The patient made an uneventful recovery in two weeks by using wet dressings of aluminium subacetate solution (0.5 per cent.). Though recurring several times, the subsequent attacks have not been so severe or so lengthy.

13 Granuloma Pyogenicum

A. MARIN (*Canadian Med. Assoc. Journ.*, September, 1932, p. 282) reviews the aetiology and treatment of granuloma pyogenicum, summing up in favour of *x*-ray or radium therapy, and recording a series of fourteen cases, each of which was cured by a single application. The condition appears as a skin outgrowth consisting of a tumour of variable size. It is due to inflammation by pyogenic cocci, and usually follows a skin puncture or slight excoriation with which is associated some suppuration. A papule appears, and gradually increases in size. At first it is soft, bleeds easily, and is either covered by a scab or is bright red. The surface which is not covered by the epidermis may be either smooth or granular, and the base be pedunculated or strangulated. The lesion ranges in size from that of a pea to that of a cherry. It may occur at any age and in both sexes, and at various sites on the skin or mucous membranes. When it appears on the lips or in the mouth it unduly alarms the cancerophobic type of patient. As regards forms of treatment other than radiotherapy, chemical caustics have to be repeatedly applied, and leave ugly scars; curetting is ineffectual unless supplemented by cauterization or irradiation; surgical removal calls for deep and extended ablation, and union is rarely by first intention, or there may be a relapse, and in any case scarring is marked, as it is also in cauterization; electrocoagulation is followed by slow healing and scarring; and ultra-violet rays do not penetrate sufficiently to destroy this deeply implanted tumour. Marin has found surface applications of radium or the insertion of radium needles effective; *x*-ray exposures were equally good. Towards the end of the week following treatment the tumour shrivels, begins to dry up, becomes flattened, and is absorbed in five or six weeks. There remains only a punctiform, flat, and whitish scar at the point of attachment of the pedicle. No repetition of the dose was ever necessary, and there was no recurrence.

Obstetrics and Gynaecology

14 Fat Content of the Liver during Pregnancy

E. DEBIASI (*Ann. di Ostet. e Ginecol.*, August 31st, 1932, p. 1153) has studied the question of fat accumulation in the liver under experimental conditions of toxicity, and prolonged action of hormones, during pregnancy in animals. The anabolic and katabolic actions of the hormones were compared with the degenerative effects of toxic products. Histological specimens of the liver of normal animals were used as controls to those obtained from animals killed and examined at various stages of pregnancy. The author has shown that the quantity of fat demonstrable by histo-chemical means normally present in the liver varies for each species. In the guinea-pig there is practically none. During pregnancy a moderate amount of fat appears, gradually becoming more evident in the later stages. The fat occurs in well-preserved cells which present no degenerative characteristics. The stellate cells do not seem to take any noteworthy part in this phenomenon of fat production. The actual quantity of fat and the number of cells infiltrated are individually very diverse; no particular central or peripheral distribution could be defined. Only in the few cases in which the fat is abundant can its tendency to collect in the cells round the bile ducts be recognized. The fat droplets are

disseminated without any connexion with the Kupffer cells. The fat distribution in the liver during pregnancy differs from that which results from the accumulation of purely alimentary fat, suggesting that there may be some toxic effect on the liver. Histo-chemical modifications of the liver appear to be subject to endocrine influence. The effects of insulin, folliculin, and hypophyseal extracts were investigated. Placental extract brings about fatty degeneration, but less severely than the lutein hormone. Treatment with a combined thyroid-hypophysis-supra-renal-ovarian extract produced simple fat infiltration in the early stages, but prolonged treatment resulted in a lesion of the hepatic cells.

15 Circular Tear of the Cervix

L. MARGULIES (*Zentralbl. f. Gynäk.*, September 17th, 1932, p. 2305) describes the case of a primipara, aged 37, whose labour commenced forty hours after rupture of the membranes. Twelve hours later, towards the end of the second stage, a dusky red ring-shaped structure presented at the vulva below the advancing head, and was identified as the central portion of the cervix uteri, including the os externum. This was two centimetres in diameter, with margins somewhat thicker than the thumb: the detachment of the central part of the cervix was complete except for a zone of three centimetres in front. An hour and a half later spontaneous delivery occurred, the loose fragment having retracted in the meantime; it was removed, after delivery of the placenta, by clamp and ligature. Six weeks later the appearance of the cervix was practically normal. Margulies states that this form of cervical laceration has been recorded in about twenty spontaneous and about twenty operative deliveries, of which over one-third were in primiparae aged more than 33. The prognosis is relatively good, only one maternal and three foetal deaths having occurred in the last thirty-two cases. In the case recorded by Margulies ante-natal examination had shown a very large and very hard portio.

16 Detection of Blood in the Abdomen

R. A. LIFVENDAHL (*Amer. Journ. Obstet. and Gynecol.*, September, 1932, p. 394) describes a sign for the detection of small amounts of free blood in the abdomen. It is emphasized that the obtaining of an accurate history and the careful conduct of the physical examination are of more value than all of the so-called pathognomonic signs yet described—such signs being always in the nature of confirmatory evidence. By correlating the clinical manifestations indicating peritoneal irritation (painful defaecation, pain on manipulation of the cervix, urinary disturbances, lower abdominal and later high abdominal pain, thoracic and shoulder pain) the author deduces that such signs are entirely due to the local irritating effect of the blood on the peritoneum, the pain varying in position according to the level which the haemorrhagic exudate has reached. The period of greatest diagnostic difficulty occurs when there are small amounts of free blood in the pelvis following the rupture of the tube, for it is at this point that all the previously mentioned evidence of peritoneal irritation confuses the diagnosis; such signs may be due to other causes, such as inflammatory conditions. In this early stage the patient usually localizes the pain in the lower part of the abdomen, either to the right or the left of the mid-line, or occasionally in the suprapubic region. If now the patient is rotated to the opposite side to that on which the pain is located, from her back on to her iliac crest, it will be observed that the subjective and objective signs have shifted to the dependent portion of the lower abdomen after a period of five to ten minutes. In other words, the position of the blood and the region of peritoneal irritation have been shifted concurrently. This test can only be expected to be positive when there is a moderate amount of free blood in the abdomen. It cannot occur, of course, when the entire peritoneum is irritated by an abdomen full of blood, nor when there is such a small amount of blood that it cannot be shifted. Two case histories are given illustrating this sign. One of these indicates that the sign may be of value in differentiating between an early ruptured ectopic pregnancy and appendicitis.

Pathology

17 The Sedimentation Rate in Juvenile Rheumatism

N. GRAY HILL (*Brit. Journ. Child. Dis.*, July–September, 1932, p. 181) investigated the erythrocyte sedimentation rate in a number of rheumatic children, of whom he records eight illustrative cases, and comes to the following conclusions. The test is of some clinical significance, and may be of real value in dealing with rheumatic children. It can be said with some degree of certainty that if the rate is below 10:20 active rheumatism (other than chorea) is not present, and that there is no real necessity for hospital treatment unless such is indicated by the cardiac condition. The rate throws no light on the extent of the cardiac involvement, but is affected by the activity of the carditis. When the readings exceed 10:20 the indications for rest in bed and more careful observation are increased. The sedimentation rate is not in his opinion a specific test, and a thorough clinical investigation can alone determine the cause of variations in the readings.

18 Pathogenesis of Carcinoma Related to Lupus Erythematosus

A. M. TISCHNENKO (*Arch. Derm. and Syph.*, August, 1932, p. 708) briefly mentions the recorded cases of carcinoma originating from lupus erythematosus, which is of exceptional occurrence, and discusses the pathogenesis of such neoplasms. Various theories on this point are cited, such as relaxation and oedema of the tissues, traumatism by therapeutic agents, lowered cutaneous resistance, and familial predisposition. While granting that these may be adjuvant factors, Tischnenko maintains that the predominant cause of cancer supervening on lupus erythematosus is radiotherapy, particularly with *x* rays. In support of this view tabulated details of eighty-two cases are given; these show a large percentage of carcinomatous supervention on the dermatitis thus treated. Four typical personal cases are also recorded. Tischnenko therefore concludes that *x*-ray treatment is contraindicated in lupus erythematosus, especially since the eruption causes no great suffering, and radiotherapy is employed chiefly for its aesthetic effects, usually with negative results.

19 Diagnosis of Anterior Poliomyelitis

F. PLAUT (*Münch. med. Woch.*, September 23rd, 1932, p. 1548) draws attention to the fact that the early diagnosis of anterior poliomyelitis is essential and only possible if the cerebro-spinal fluid is examined. The typical findings are: the pressure is increased, the fluid is clear and colourless, and there is a moderate increase of the number of cells (15 to 20 per c.mm.). The amount of globulin is slightly increased; the total proteins are increased (100 mg. per cent. and over). The amount of sugar is normal. A differential diagnosis between encephalitis and poliomyelitis is usually possible. In the first there is only a slight increase in the total protein content, whereas the sugar content is increased. If there is a great increase of cells and the sugar content is above 30 mg. per cent. the diagnosis of tuberculous meningitis is almost certain. In suspected cases of anterior poliomyelitis it is not enough to depend on the increase of cells, since in 25 per cent. of cases this is absent. If there is a total increase of protein of 50 mg. per cent. or over, the patient must be injected with the serum of a convalescent case. A further indication for serum treatment is a positive mastic or gold-sol reaction. Patients are usually able to stand lumbar puncture well if the cerebro-spinal fluid is withdrawn slowly. Some authors believe that there is definite danger in removing large amounts of cerebro-spinal fluid in cases of anterior poliomyelitis—according to Plaut a groundless fear. In these the micromethods of examination may be used, only 0.6 c.cm. of fluid being necessary.

NATURALLY RICH IN VITAMIN "D"

Improving Milk Supplies

New Bonus Scheme for Farmers

CLEAN MILK is an expensive commodity to produce. But only the very best is good enough for COW & GATE, who have therefore always demanded a high quality and special handling of the milk which is the source of their well-known products. Careful laboratory examinations of each churn of milk as it arrives at the factories is insisted on, and every producer is forced to use the special Cow & Gate strainer on the farm. Realizing that educational work and supervision can only be effective up to a point, and that in order to ensure progress beyond this, monetary inducement is necessary, Cow & Gate have now devised a Quality Bonus Scheme.

Starting October 1st this year, all milk received has been given marks according to bacterial count, fat content, solid content, and visible sediment, and the producers heading the list are being rewarded by a Bonus on each month's supply of between ½d and 1d per gallon. This has meant as much as £12 a month to a careful farmer. We feel the Profession which is always so interested in the improvement of our milk supplies should know of this step, which we feel is definitely a progressive one.

SALTAIR SURGICAL SERVICE

SALT'S COLOSTOMY BELTS

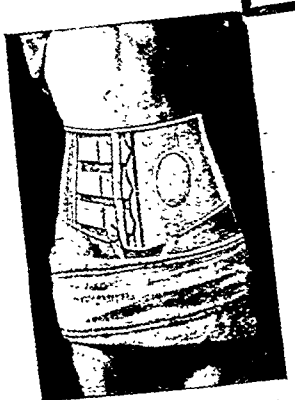

ILLUSTRATION SHOWS BELT WITH CUP ONLY.

From the first these Belts have met with deserved commendation and given very satisfactory results. The latest models, however, are improvements upon what were already excellent productions. They can be supplied with sterilizable Rubber Cup only (indicated in cases where the faeces are of a solid nature or small in amount), or with sterilizable Receiver and Bag. In the latter the Receiver is now moulded from one piece of Rubber and the weight is reduced. The Bag can be quickly detached without removal of belt. Odour is reduced to a minimum owing to the absence of crevices. Further details of these Belts will be gladly sent on request.

BELOW IS BELT WITH DETACHABLE RECEIVER AND BAG.

THE DOCTORS' SPECIAL POLICY

An additional encouragement is now offered to Medical Motorists to obtain a Doctors' Special Policy, in the form of progressive reductions in premiums by way of increased "No-Claim Bonus" rising to 20% at the end of a period of three years.

This is a new feature of the Doctors' Special Policy arranged by the Medical Insurance Agency to give comprehensive cover, with security, at minimum premium rates.

Further, to the improved "No-Claim Bonus" and the usual Agency Rebate of 10%, a new Special and Additional "No-Claim Bonus" of 2½% has been granted by the Committee of Management, so that the total allowances may reach 32½%.

The chief asset of a Motor Car Policy is its Claims Settlements' Service. The Service rendered under the Doctors' Special Policy is **second to none.** The Agency knows only too well the importance of speedy repairs to Doctors' Cars and the quick return of the Car, consistent with efficient workmanship.

No loss of Bonus on Transfer.

DINNEFORD'S

A safe and simple antacid which is also a gentle laxative, must necessarily be of great value to the Medical Profession for administration to ladies and children and all who are constitutionally delicate. Extensively prescribed and used by the Medical Profession for a century and still incomparably better and safer than powdered magnesia.

PURE FLUID **MAGNESIA**

DINNEFORD'S is immensely useful in the nursery, too; when mixed with infants' food it prevents many of the troubles due to acidity, flatulence, etc. As a reliable and safe solution which may be freely used for many ailments, we would request your kind consideration of DINNEFORD'S, as occasion offers.

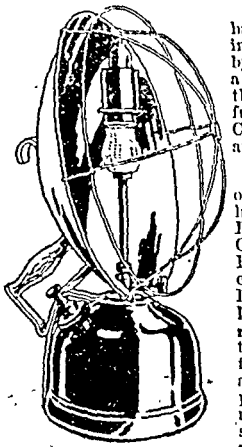
THE TILLEY RADIATOR

AS A SOURCE OF RADIANT ENERGY FOR TREATMENT OF DISEASE



Height 16½ in.

Medical experience has shown that the infra-red rays emitted by sources of heat have a beneficial effect in the treatment of painful affections, such as Chronic Rheumatism and Neuritis.

Carrying out tests on various sources of heat at the London Light and Electrical Clinic, Sir Leonard Hill found that the emission of the Tilley Radiator was **particularly rich in infra-red rays,** which penetrate the skin and excite flushing and other reactions which relieve pain. To secure these results the Radiator should be brought as near to the painful part as can comfortably be borne. Exposure to the rays may be prolonged safely for half an hour or more.

Here, then, is convincing proof of the usefulness of the Tilley Radiator in every home—not only for the genial heat it provides, but also for the benefits which can be obtained by its use medically.

Its portability and absence of connections make the Radiator eminently adaptable to all circumstances.

BRITISH MADE THROUGHOUT.

The price of the Tilley Radiator is 45/- Enquire Local Ironmonger. If any difficulty, Radiator will be sent post free on receipt of remittance, or C.O.D., post and charges paid.

NORTH BERWICK

As a HEALTH RESORT in WINTER it is not so well-known as it ought to be. AIR IS DRY AND BRACING; RAINFALL ONLY HALF THE AMOUNT as on South Coast resorts; FOG CONSPICUOUS BY ITS ABSENCE.

It is no uncommon experience to read of England enveloped in fog while North Berwick is bathed in glorious sunshine.

The Marine Hotel there offers Winter visitors its luxurious comfort and excellent cuisine at moderate inclusive charges from £5 5/- per week.

For particulars apply to the Manager

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains spec[illegible] by various methods, including Turkish and Russan baths, the [illegible] Douche, Scotch Douche, Electrical bath, Plombières treatment, et[illegible] a Dental Surgery, an X-ray room, an Ultra-violet Apparatus, [illegible] and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES suffering from mental and nervous diseases, either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary and Temporary Patients received.

Tel. 64117. For terms, etc., apply to the Medical Superintendent.

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

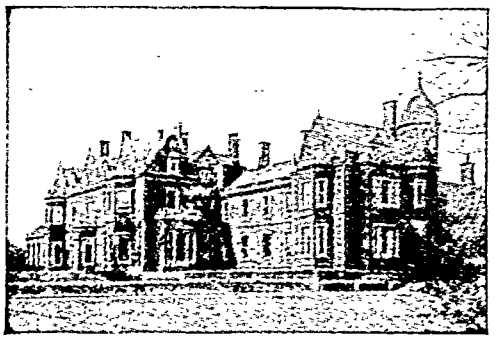
(Postal Address)—WOODBRIDGE, SUFFOLK.

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16. *(Toll Call from London.)*



RENDLESHAM HALL.

To those desiring to be near London—

The Mansion, Beckenham Park, Beckenham,

as carried on for the last twenty years, is available. Booklets and particulars from the Resident Medical Superintendent.

Telephone: BECKENHAM 1648. *Telegrams:* NOROTORIUM, BECKENHAM.

Proprietors: **The Norwood Sanatorium, Limited.**

The MAUDSLEY HOSPITAL

DENMARK HILL, S.E.5.

Telephone: RODNEY 2101—4.

Golf (Moor Park, Sandy Lodge) close by. For particulars apply to—F. S. D. HOGG, M.R.C.S., &c., Resident Med. Supt. Telephone: 16 RICKMANSWORTH.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings; all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board, and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. Telegrams: ASTLE, RUTHIN. Telephone: RUTHIN 66.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Welbeck 6901

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.) M.C.CANTAB. M.S.LONDON. F.R.C.S.EDINBURGH.

And all other Surgical Degrees and Diplomas.

¶ The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

¶ Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

¶ The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

¶ The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

ROYAL LONDON OPHTHALMIC HOSPITAL

(Moorfields Eye Hospital),
City Road, London, E.C.1.

GIFFORD EDMONDS PRIZE IN OPHTHALMOLOGY.

The Prize of £100 awarded every two years is offered for the best Essay on a subject dealing with Ophthalmology and involving original work, and is open to any British subject holding a medical qualification.

The subject for the next Essay is:—
"The Comparison between the Visual Results obtained by various Methods employed for the Treatment of Concomitant Strabismus."

Preference will be given to original work based on any branch of the subject, rather than to compilations of the writings of previous observers.

Essays must be sent in not later than December 31st, 1934.

A leaflet giving full particulars of the prize may be obtained from the Secretary, Royal London Ophthalmic Hospital (Moorfields Eye Hospital), City Road, London, E.C.1.

EPSOM COLLEGE.

COUNCIL EXHIBITIONS.

An EXAMINATION will take place in due course for the admission of two or possibly three boys as COUNCIL EXHIBITIONERS. The fee payable is £75 a year, instead of the usual fee of £155. Candidates must be the sons of such duly qualified Medical Men as shall, in the opinion of the Council, be among the less fortunate members of their Profession. They must be over 12 and under 14 years of age on January 1st, 1933. Application forms are obtainable on request, and must reach me at the College Office, 49, Bedford Square, W.C.1, duly completed by the morning of January 31st, 1933.

W. L. GIFFARD (Major),
Secretary.

49, Bedford Square,
W.C.1. January, 1933.

THE HOSPITAL FOR SICK CHILDREN, Great Ormond St., London, W.C.1

This Hospital contains 252 beds with an average admission of over 7,000 in-patients per annum; whilst in the out-patient department about 30,000 new patients are seen each year. The Medical School is recognized by the Universities of Oxford, Cambridge, and London, and by the Conjoint Board of England as a teaching institution where students receive instruction in the treatment of Diseases of Children for such a period as is required by the Regulations of the Conjoint Board.

Post-graduate instruction, open to all qualified medical men and women, is given daily in the wards, out-patient department, operating theatre, and post-mortem room by members of the visiting staff. Clinical clerkships in the wards and clinical assistantships in the out-patient department are also available for post-graduate students. Fees: One month's ticket £2 2s. Three months' ticket £5 5s. Perpetual ticket £10 10s. Reduced fees for Clinical Clerks and Dressers for one month's attendance £1 1s. Clerks attend for about four hours daily.

POST-GRADUATE COURSES ON DISEASES OF CHILDREN are held twice yearly in spring and autumn. Each course lasts a fortnight and consists of 50 Clinical lectures and demonstrations and 6 Pathological demonstrations. Fees for each course £6 6s.

The next course will start on May 15th and end on May 27th, 1933.

SPECIAL COURSES IN PRACTICAL PATHOLOGY, consisting of 6 demonstrations, are also given at the Hospital. These courses demonstrate such methods as can be usefully carried out away from a laboratory, and which are of general application. Fees for each course £2 2s.

Four of these courses will be held in 1933 lasting one week each and commencing February 6th, June 12th, September 14th, and December 4th respectively. Further information may be obtained from the Secretary at the Hospital.

H. F. RUTHERFORD, Secretary. W. G. WYLLIE, M.D., F.R.C.P., Dean.

Post-Graduate Teaching, West London Hospital.

Continuous Clinical Instruction daily from 10 a.m. to 4 p.m.—Post-Graduates may enrol at any time for any period from 1 week to 3 months.—Special facilities for "Study Leave," and for those wishing to take a course under the "Grant-aided Scheme for Post-Graduate Study by Insurance Practitioners."—Anaesthetic Courses.—Clinical Assistantships.—Annual Membership Tickets at Special Terms available for General Practitioners who wish to attend the Hospital Practice at irregular intervals.

Prospectus from the DEAN, West London Hospital, Hammersmith, W.6.

POST-GRADUATE COURSES:

Open only to Members of the Fellowship of Medicine. Annual Subscription £1 1s.

CARDIOLOGY (National Heart Hospital, January 16th-27th); X-RAY DEMONSTRATION (Medical Society, January 20th, 4.30 p.m. to 6 p.m., especially for M.R.C.P. candidates); CASE DEMONSTRATION (Lambeth Hospital, January 13th, 2 p.m.); LECTURES on "Practical Problems in Medicine and Surgery" (Medical Society, Tuesday, at 4 p.m., beginning January 17th).

Panel of Teachers for personal tuition always available.

Apply—
FELLOWSHIP OF MEDICINE, 1, Wimpole Street, London, W.1. (Langham 4266.)

NORTH LONSDALE HOSPITAL, BARROW-IN-FURNESS. (152 Beds.)

HOUSE PHYSICIAN and CASUALTY OFFICER. (Male appointments.)

Applications are invited for the above resident appointments from fully qualified practitioners experienced in the administration of anaesthetics. Duties to commence on February 1st, 1933. Salaries £175 and £150 per annum respectively, with board, residence, and laundry.

Applications, stating age, qualifications, experience, and nationality, accompanied by copies of three recent testimonials, should be sent to the Secretary not later than January 16th, 1933.

URBAN DISTRICT COUNCIL OF ENFIELD.

ASSISTANT MEDICAL OFFICERS OF HEALTH.

The Urban District Council invites applications for the appointment of Assistant Medical Officer of Health for Maternity and Child Welfare purposes. Two such appointments will become vacant on April 1st next.

Applicants (female) should have had previous experience in dealing with diseases of babies and children, and of ante-natal and post-natal work.

The appointments will be part-time and the persons appointed will be required to attend at the Centres for 2½ hours on four afternoons and one morning per week. In addition, the persons appointed will be required to attend on alternate Saturday mornings at the Maternity and Child Welfare Dental Clinic for the purpose of administering anaesthetics, and should have had special experience of this work.

The persons appointed will be required to carry out their duties under the supervision of the Medical Officer of Health.

The salary will be £300 per annum, and four weeks' holiday per annum will be allowed.

Applications, stating name and address, age, whether married or single, degrees, diplomas, and previous experience, and accompanied by copies of three recent testimonials, must be delivered to the undersigned marked "Assistant M.O.H.," not later than noon on Saturday, January 21st.

Candidates canvassing Members of the Council, directly or indirectly, will be disqualified.

Public Offices, Enfield, Middlesex. December 30th, 1932.
KENNETH TANSLEY, Clerk to the Council.

LONDON COUNTY COUNCIL.

Applications invited for appointment to position of RESIDENT MEDICAL SUPERINTENDENT in Public Health Department for duty at St. Giles' Hospital (820 beds), Brunswick Sq., Camberwell, S.E. Duties also include those of Medical Officer of (1) Camberwell Institution and (2) Peckham Children's Homes. Person appointed will be under direction of Medical Officer of Health and must, if required, assist at other Council establishments. Salary £1,300 by £50 to £1,550 a year, plus £50 a year and £25 a year for duties at Camberwell Institution and Peckham Children's Homes, respectively. Unfurnished house or quarters provided free of rates, etc., valued provisionally at £100 a year. Cash remuneration is subject to temporary reductions. Candidates, other than members of the Council's medical staff, must not be over 55 years of age, and must be fully qualified medical practitioners for at least five years and have been house physician or house surgeon in public general hospital and have experience of hospital administration.

Application forms obtainable (stamped addressed foolscap envelope necessary) from Clerk of the Council, County Hall, S.E.1 returnable by January 16th, 1933. Canvassing disqualifies.

LONDON COUNTY COUNCIL.

Applications invited for appointment to the position of RESIDENT ASSISTANT MEDICAL OFFICER (Grade II) (man only) at QUEEN MARY'S HOSPITAL, SIDCUP (for convalescent patients). Salary £250 a year, together with board, lodging, and washing (subject to temporary reductions). Appointment at this hospital for one year only and not renewable.

Candidates must be registered Medical Practitioners of at least one year's standing, and have held a resident appointment in a general hospital for six months.

The duties are assigned by the medical superintendent, and include if necessary assistance at other establishments under the control of the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 3a), County Hall, Westminster Bridge, S.E.1, returnable by January 13th, 1933. Canvassing disqualifies. Further inquiries should be addressed to Medical Superintendent at the Hospital.

LONDON COUNTY COUNCIL.

Applications invited from registered Medical Practitioners for appointment as CLINICAL ASSISTANT at ST. STEPHEN'S HOSPITAL, Fulham Road, S.W.10. Salary £100 a year, together with meals when on duty, subject to temporary reduction. Appointment is for six months in the first instance, but may be extended for a further period of six months. Duties are assigned by the Medical Superintendent and include, if necessary, assistance at other establishments under the control of the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 3a), County Hall, Westminster Bridge, S.E.1, returnable by January 13th, 1933. Canvassing disqualifies.

Further inquiries should be addressed to Medical Superintendent at the Hospital.

THE MIDDLESEX HOSPITAL AND MEDICAL SCHOOL, W.1.

Applications are invited for ONE MEDICAL REGISTRARSHIP.

The Registrars are attached to Clinical Units of the Hospital and are responsible for the Clinical Notes, the carrying out of clinical and pathological examinations, the preparation of material for demonstration, and the co-ordination of the work in the Bland-Sutton Institute of Pathology with that in the Wards.

The appointment will be from March 12th to December 31st, 1933, and the successful applicant will be eligible to apply for re-appointment and to hold office for two further consecutive years. He will be required to attend at the Hospital daily from 10 a.m. to 6 p.m. Salary £300 per annum.

Further particulars may be obtained from the undersigned, to whom applications, with copies of not more than three testimonials, must be sent before noon on Saturday, February 4th.

S. R. C. PLIMSOLL, Secretary-Supt.

CITY AND COUNTY OF NEWCASTLE-UPON-TYNE.

NEWCASTLE GENERAL HOSPITAL. (650 Beds.)

TWO HOUSE SURGEONS AND ONE HOUSE PHYSICIAN (Male).

The above posts will become vacant on February 1st, 1933, and applications are invited from duly qualified and registered Medical Practitioners.

The salary in respect of each of the appointments, which are tenable for six months, is at the rate of £150 per annum, with board, lodging, etc.

Applications, stating age and qualifications, together with copies of not more than three recent testimonials, to be addressed to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne, not later than January 12th, 1933.

HERTFORDSHIRE COUNTY COUNCIL.

CELL BARNES COLONY FOR MENTAL DEFECTIVES.

POST OF DEPUTY MEDICAL SUPERINTENDENT.

Applications are invited from duly qualified men who should be under 40 years of age and must have had satisfactory experience in the care and treatment of the mentally defective. The post is resident, and is pensionable under the A. & C.I.O. Pensions Act, for which purpose the selected candidate will be required to pass a medical examination.

The salary and emoluments are of a total value of £600 per annum, rising by four increments of £25 to £700 per annum, subject to a temporary reduction of 7½ per cent. on the salary.

Application forms, with full information, may be obtained from the Medical Superintendent, Cell Barnes Colony, St. Albans, Herts, and must be returned to him, not later than Saturday, January 28th.

WEST LONDON HOSPITAL, Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of ASSISTANT GYNAECOLOGIST.

Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh, or Ireland, or a Fellow or Member of the Royal College of Physicians of London. The successful candidate will be required in addition to his other duties to undertake such teaching for the Post-Graduate College as the Board may approve.

Applications, accompanied by copies of testimonials, should reach me not later than Thursday, February 2nd. Candidates must attend a Special Meeting of the Medical Council on Friday, February 3rd, at 4.30 p.m. and prior to that date call upon and send copies of applications and testimonials to each member thereof. They must not canvass Members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and if so notified, be in attendance at a Special Meeting of the Board at 5.30 p.m. on Tuesday, February 7th, when the election will be made.

H. A. MADGE, Secretary.

DOWN MENTAL HOSPITAL, DOWNPATRICK, NORTHERN IRELAND.

Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.
Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUM TENENS.

Assistants and Locum Tenens can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Accounts, etc.

Practices and Partnerships for Disposal. Full particulars sent free.

1. WITHIN TWENTY MILES OF LONDON.—PARTNERSHIP.—A share, producing about £850 p.a., is offered (after a preliminary assistantship of three months), in a sound and increasing mixed-class Practice, having good scope. Large panel. Suitable house available, on rental. Premium 3 years' purchase. Scottish Graduate preferred.
2. CENTRAL LONDON.—Middle-class PRACTICE, producing about £750 p.a., with panel of 350. Fees 3/6 upwards. Midwifery not encouraged. Suitable flat containing sitting room, 2 bedrooms, etc., surgery, and waiting room. Rent on lease £120 p.a. Premium £800, or near offer.
3. MIDLAND CITY.—Old-established good-class PRACTICE situated in residential district, and producing about £1,600 p.a. net. Visits 3/6 to 21/-. Excellent house with all conveniences, nice garden, garage, etc. Vendor's leasehold property (25 years to run). Price for Practice and lease £3,250.
4. SOUTH-WEST OF ENGLAND.—Old-established easily worked PRACTICE, situated in one of the best residential districts of a large city, *is for disposal* in consequence of ill-health of Vendor. Income about £1,000 p.a., with excellent scope. Good house available. Educational facilities exceptional. Knowledge of Eye work would be an asset.
5. LANCS. — LARGE TOWN. — Old-established upper and middle-class PRACTICE, situated in purely residential district and averaging about £1,700 p.a. including appt. of £150, and panel of 700. Visits 5/- upwards. Very little midwifery at 5 to 10 guineas. Expenses low. Excellent and well-built house, ideally situated, having ample accommodation (surgery, waiting room, and dispensary, 3 reception, 5 bedrooms, etc.). Rent on lease £120. Premium £2,500. Good educational facilities.
6. YORKSHIRE.—PARTNERSHIP.—A one-fourth share, with increase later, is offered in a very sound old-established general Practice, situated in favourite country town, within easy reach of coast. Gross cash receipts for the last three years have averaged £5,700, and for the immediate past twelve months £4,180. Panel of 2,000, and appts. bring in about £500 p.a. Fees 5/- to 21/-. House contains 3 reception, 5 bedrooms, etc. Electric light; garden. Garage. Can be rented at £46 p.a. Or other houses available. Excellent sport and good schools. Premium for share 2 years' purchase.
7. CHESHIRE.—NEAR COAST.—Old-established middle and working-class PRACTICE, averaging for the past three years over £1,300. Panel of 550. Fees from 3/6. Good house, with 3 reception, 7 bedrooms, etc. Price for freehold £1,200, part on mortgage.
8. PARTNERSHIP.—ANGLO-WELSH BORDER.—A one-third share, with increase later, is offered in an old-established good mixed Practice, situated in pleasant country town, amidst beautiful surroundings. Gross cash receipts for last 12 months £1,800, of which £800 is from panel and appts. Purchaser should be interested in medicine as Vendor undertakes surgery. Suitable accommodation obtainable. Premium £900, part by instalments if desired.
9. LONDON, WEST CENTRAL.—Better-class PRACTICE, producing for last 12 months £600, including panel of 160. Fees usually 5/- to 21/-, and a few at 3/6. Midwifery 5 to 15 gns.; about six cases yearly. Maisonette, containing waiting room, consulting room and dispensary, sitting room, bedroom, kitchen, and bathroom, etc. Can be rented on lease, and part sublet if wished. Premium £650.
10. SOUTH-WEST OF ENGLAND.—LARGE TOWN.—ASSISTANTSHIP with view to PARTNERSHIP. Practice is very well established, chiefly middle-class, with large panel. Fees 3/6 to 10/6. Ingoing Partner should be between 24 and 26 years of age, with good Hospital experience, etc. and Public School education. Suitable house available during *preliminary* assistantship.
11. SOUTH CORNWALL.—Old-established unopposed PRACTICE, situated in very pleasant district, with mild climate. Gross cash receipts approximately £950 to £1,000 p.a., including £275 from panel and appointments. Fees 5/- to 7/6. Very nice house, overlooking the sea, containing 3 *reception*, 4 bedrooms, 2 *maids' rooms, bathroom*, etc., and professional accommodation. Garage. Garden. Freehold for sale, £300 down, and balance on mortgage. Premium £1,400, to include drugs, etc. Good scope for increase.
12. CHANNEL ISLANDS.—Well-established better-class PRACTICE, averaging over £600 p.a. Good fees. Not much midwifery, but scope for this work if wished. Suitable house on rental. Moderate premium.
13. NORTH DEVON.—Very old-established unopposed country PRACTICE in beautiful district, within easy reach of the sea. Cash receipts over £900, including panel and appointments about £500. Excellent residence (3 reception, 6 bedrooms, bathroom, etc.). About half an acre of garden, tennis lawn, etc. Garage. Water laid on and main drainage. Rent on lease £60 p.a. Premium £1,450. Good hunting, shooting, fishing. Educational facilities
14. SOUTH-WEST OF ENGLAND.—Coast Town.—Middle and working-class PRACTICE, rapidly increasing, and producing about £600 p.a., including panel of 400. House can be rented at £75 p.a., and contains 2 reception, 5 bedrooms, etc. Electric light. Garden. Prem. £750.
15. SURREY.—Growing residential neighbourhood, within easy reach of London.—Mixed-class PRACTICE, producing about £1,000 p.a., and offering good scope. Panel of 400. Fees from 3/6. Suitable house with 2 reception, 3 bedrooms, etc. Price for freehold £1,400, part on mortgage. Premium 2 years' purchase.
16. PARTNERSHIP.—NORTHERN COUNTIES.—A one-third share (with increase later) is offered in a good middle-class non-panel Practice, situated in a prosperous town, with pleasant surrounding country. Gross cash receipts average about £3,500 p.a. Fees 3/- upwards. Suitable house, with 2 reception, 4 bedrooms, etc., and small garden. Price £1,200, part on mortgage. Excellent sport and educational facilities. Premium for share, £2,000.
17. KENT.—Good-class NUCLEUS, non-dispensing, in pleasant residential district within 20 minutes' run of London. Receipts between £350 and £400, and offering exceptionally good scope. Fees 10/6 to 21/-. Good house, ideally situated, with ¾ of an acre of garden, tennis court, etc. Price freehold £2,800, to include premium for Practice. Excellent educational facilities.
18. MIDDLESEX.—Residential District.—Mixed-class PRACTICE, averaging £537 p.a., including panel of 150. Fees from 3/6. Corner house, with 2 reception, 5 bedrooms, and professional accommodation, with separate entrance. Freehold. Golf and other sport. Very good schools. Price for practice and house £2,100, or near offer, part on mortgage.
19. PARTNERSHIP.—LONDON, SOUTH-WEST.—A one-half share is for disposal in an old-established very good middle-class Practice, in pleasant residential open suburb, within easy reach of City and West End. Average gross cash receipts for past 3 years £2,557. Panel of 1,400. Visits from 4/-. Not much midwifery, from 3 to 7 gns. House contains 2 reception, 6 bedrooms, etc., and professional rooms. Garden. Good schools and sport. Premium £2,559.
20. WESTERN SUBURB. — Old-established and mainly middle-class PRACTICE, worth about £400 p.a. and offering scope. Panel of 108. Visits 5/6 to 21/-. Midwifery 5 gns upwards, not encouraged. Good house (6 bedrooms, etc.) with very nice garden and garage. Price leasehold (42 years to run) £1,850, £1,200 on mortgage. Premium moderate.
21. NEW ZEALAND (North Island).—Old-established non-dispensing PRACTICE, situated in increasing county town, amidst beautiful surroundings. Cash receipts for past five years average £1,400 p.a. Attractive residence standing in an acre of garden, with tennis court, orchard, etc. Electric light. Can be leased. Educational facilities, sport, etc. Premium £1,000.
22. *SANATORIUM.—SOUTH-WEST OF ENGLAND, and within 20 miles* of County Town. Very old-established. Receipts for the past three years average over £9,000 p.a. Patients middle and upper-class. Accommodation for 45. Price for goodwill, freehold house, with large grounds, furniture, fixtures, etc., is moderate.
23. MANCHESTER. — Suitable Lady Doctor. — Middle and working-class PRACTICE, averaging £670 p.a., including panel of 450. Fees 2/6 to 7/6. House contains 5 reception, 5 bedrooms, separate surgery entrance, etc. Bathroom. Electric light. Garage. Rent on lease £80 p.a. Premium 1½ years' purchase. Very large scope for increasing the Practice as Vendor has only worked it as a part-time one.

ASSISTANTS REQUIRED.—(1) *MIDDLESEX.*—Well-established PRACTICE, with substantial panel and good appts. Outdoor ASSISTANT, with view to Partnership. Suitable house on rental. Must be English and well-experienced. (2) GLOS.—Indoor. £250 £300 p.a. Good mixed-class Practice, with pleasant surroundings.

WANTED TO PURCHASE.

1. LONDON, or within twenty miles.—Good mixed-class PRACTICE, with panel of about 1,500. Income £1,200 to £1,500. Fair-sized house and garden.
2. LONDON SUBURB or good Provincial Town.—Better-class PRACTICE averaging about £1,500 to £2,000 p.a., with fair-sized panel. Small house sufficient. Ample capital.
3. SOUTH OF ENGLAND or RESIDENTIAL SUBURB OF LONDON.—*Open, better-class Practice, offering scope for development.* Substantial panel required. Nice house and garden. Ample capital for suitable practice or partnership.
4. LONDON or SUBURBS, preferably West or South-West.—PRACTICE or PARTNERSHIP producing about £1,200 p.a. or less if scope. Fair-sized house with garden.
5. MIDLANDS OR SOUTH OF ENGLAND (not Devon or Cornwall).—Country PRACTICE bringing in from £750 to £800 p.a. Small house to rent, with good grounds. Must be within reach of good fishing.
6. MANCHESTER or SUBURBS.—Well-established PRACTICE, in pleasant district. Income from £1,000. Good panel essential. Capital available.

Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

—THAT ENDS WELL

YOUR patient begins with a tablespoonful continues with a teaspoonful and finally stops it altogether Surely, there is no clearer way to demonstrate the therapeutic value of AGAROL in the treatment of constipation.

Besides, Agarol Brand Compound is so easy to take. No oiliness, no artificial flavouring to get used to. It can be mixed with water, fruit juices, milk, with semi-solid food, used as a salad dressing in place of mayonnaise. Serves you better—serves your patient better.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

A supply gladly sent for trial.

AGAROL *for Constipation*

BRAND COMPOUND

A PLAIN STATEMENT OF FACTS

FOR THE ATTENTION OF THE MEDICAL PROFESSION

THERE is no mystery about "THE DOCTOR'S CHINA TEA" Good black China Tea has far less tannin than any ordinary tea. It has been proved by analysis that even the best teas grown outside China contain at least 50% more tannin than good China tea. You are fully aware that tannin is the cause of many gastric and nervous disorders. You may not be aware of the fact that many thousands of medical men—whose names we obviously cannot publish—have borne unsolicited testimony to the efficiency of "THE DOCTOR'S CHINA TEA" in cases where to prohibit tea altogether would have been detrimental, and yet where the excess tannin of ordinary teas was definitely harmful. "THE DOCTOR'S CHINA TEA" can be safely prescribed in cases of dyspepsia and other gastric troubles, and can be safely recommended to expectant mothers. In order that you may form your own opinion upon "THE DOCTOR'S CHINA TEA" may we send you a free ½-lb. sample?

THE DOCTOR'S CHINA TEA

Priced at 2/8, 3/2, and 3/10 per lb. and a super quality at 4/4 per lb.

J. & A. CHURCHILL

For Students — **SEVENTEEN NEW BOOKS** — *For Practitioners*

THE MEDICAL DIRECTORY, 1933

89th Annual Issue. 2,500 pages. 55,952 names. 36s.

Including "British Spas and Seaside Resorts." Much enlarged and illustrated throughout with 133 Photographs. Edited by R. FORTESCUE FOX, M.D., F.R.C.P.

"The Medical Directory like the City of London, is a peculiarly British institution which fills the discerning foreigner with envy. . . . Dr. Fortescue Fox's section of the book is now much larger and more attractive than ever before. It forms a valuable guide to the climatic resorts and their medical values and uses in the prevention and cure of disease."—B.M.J., Dec. 17th, 1932.

THE BIOCHEMISTRY OF MEDICINE

By A. T. CAMERON, D.Sc., F.I.C., Prof. of Biochemistry, Univ. of Manitoba, and C. R. GILMOUR, M.D., C.M., Prof. of Medicine, Univ. of Manitoba. 31 Illustrations. 21s.

HALE-WHITE'S MATERIA MEDICA

New (21st) Ed. Based on the new B.P. Revised by A. H. DOUTHWAITE, M.D., F.R.C.P., Asst. Physician, Guy's Hosp. 10s. 6d.

This popular work has been completely revised, with new type, enlarged page and improved binding. 90,000 *copies of this famous book have been sold.*

MEDICINE—*Essentials for Practitioners and Students*

By G. E. BEAUMONT, D.M., F.R.C.P., Physician, with Charge of Out-patients, Middlesex Hospital. 61 Illustrations. 21s.

THE SCIENCE AND PRACTICE OF SURGERY

By W. H. C. ROMANIS, M.B., F.R.C.S., and PHILIP H. MITCHINER, M.D., F.R.C.S., Surgeons, St. Thomas's Hospital. 4th Edition. 752 Illustrations. 2 Volumes. 28s.

A TEXT-BOOK OF SURGICAL PATHOLOGY

By C. F. W. ILLINGWORTH, M.D., F.R.C.S., and B. M. DICK, M.B., F.R.C.S., formerly Tutors in Clinical Surgery, The Royal Infirmary, Edinburgh. 290 Illustrations. 36s.

RECENT ADVANCES IN PATHOLOGY

By GEOFFREY HADFIELD, M.D., F.R.C.P., Professor of Pathology in the University of London, and L. P. GARROD, M.B., M.R.C.P., Bacteriologist and Lecturer in Bacteriology, St. Bartholomew's Hospital. 67 Illustrations. 15s.

RECENT ADVANCES IN OBSTETRICS AND GYNAECOLOGY

By ALECK BOURNE, M.B., F.R.C.S., and LESLIE WILLIAMS, M.D., F.R.C.S., Obstetric Surgeons, St. Mary's Hospital. 3rd Edition. 87 Illustrations. 12s. 6d.

50th YEAR OF PUBLICATION.

THE EXTRA PHARMACOPOEIA

VOL. I — 20th EDITION — NOW READY.

27/6 net; 28/- post free throughout the world.

An up-to-date book of reference containing concise and easily-found information concerning the clinical use of modern chemicals and drugs—their characters, dosage, methods of use, etc. The Posological Index contains over 12,000 items. A synopsis of the principal changes and additions in the new B.P. is incorporated.

Descriptive leaflet on request.

EXTRACTS FROM PRESS NOTICES.

"The long and successful career of the Extra Pharmacopoeia is the best proof that it has catered for a real need in the Medical Profession."—BRITISH MEDICAL JOURNAL.

"It contains more information on all aspects of drugs than any book of its kind. . . . Few medical men can afford to be without this valuable work."—THE LANCET.

"Is invaluable to the daily work of every practitioner and every pharmacist."—THE PRACTITIONER.

"The new edition well reflects the present position of therapeutics. It is still the handy and useful desk companion it has been in the past."—THE PRESCRIBER.

"The Extra Pharmacopoeia maintains its old-established excellence; it stands alone, unequalled by any other work."
—MEDICAL PRESS AND CIRCULAR.

"A model of condensation, exposition, and practical service . . . an indispensable and unique work of reference."
—BRITISH JOURNAL OF TUBERCULOSIS.

"The book is in a greater degree than ever a mine of information for the medical man, pharmacist, and analyst."
—BRITISH JOURNAL OF DERMATOLOGY.

"A tried and trusty friend. . . . To condense such a mass of information into such a handy volume is no mean achievement."
—THE MEDICAL OFFICER.

"This remarkable and ingenious work . . . will be found indispensable for reference purposes."—MEDICAL WORLD.

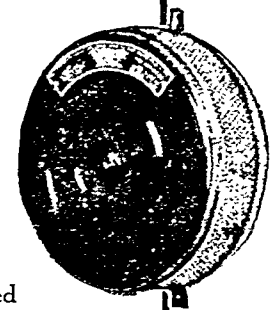
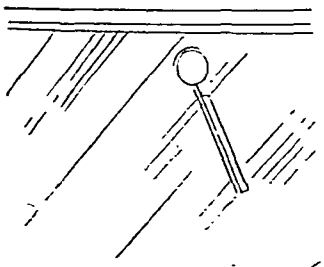
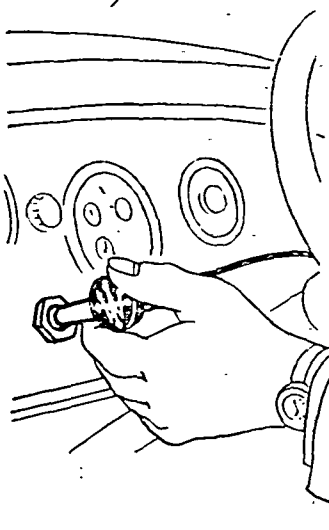
Just Plug In







When you drive your car into the garage just reach out your hand, plug in to the socket on the dashboard, switch on, then leave it—that's all. It will take you two seconds, and then you can be certain of something in the battery just when you need it. That is what the WESTRIC CHARGER does for the car owner. Two types are available, one for six-volt, and one for twelve-volt batteries. Just fix the battery socket on your dashboard, mount the WESTRIC CHARGER in the garage and plug in whenever needed. The cost of running a WESTRIC is as low as one penny per night of twelve hours.

Price, complete with battery socket, for Great Britain and Northern Ireland - - - - - **75/-** nett.

For A.C. supplies 200/250 volts—40/100 cycles.

Other supplies 10% extra. State whether for 6 or 12 voltage.

Send for illustrated folder, B.M.J. 1, giving full particulars.

INSULIN 'A.B.'

The world-wide supremacy of Insulin 'A.B.' is due to its unequivocal purity no less than to its well-known potency and stability under all conditions.

Insulin 'A.B.' contains the minute quantity of phenolic preservative originally recommended by the Medical Research Council and still considered necessary by bacteriologists (*Lancet* Sept. 12, 1931, pp. 582-584) as a complete safeguard against the development of bacteria that may be accidentally introduced during self-administration.

Supplied in three strengths:

20 units per c.c. Packed in bottles containing:
5 c.c. (100 units) - - 2/- each
10 c.c. (200 „) - - 4/- „
25 c.c. (500 „) - - 10/- „

A Distinct Advance Over Preparations of Acetyl-Salicylic Acid

Acetyl-salicylic acid possesses a notable disadvantage. Physicians have proved that it cannot be tolerated by patients suffering with a delicate stomach. Consequently, the value of this medicament in the wide field in which it is indicated is very seriously reduced.

"Alasil" completely overcomes this objection. By combining calcium acetyl-salicylate with "Alocol," unfavourable secondary action upon the stomach is prevented. This beneficial influence is undoubtedly due to the presence of "Alocol" (Colloidol Hydroxide of Aluminium), which preparation has brilliantly stood the test of practice in the treatment of hyperacidity and other ill conditions of the gastric tract. "Alasil" is therefore a triumph over acetyl-salicylic acid. It enables higher doses to be administered and maintains the patient's system under its influence for a greater length of time. Analgesic, Antipyretic, and Sedative, "Alasil" is indicated in all cases where acetyl-salicylic acid has been used heretofore.

A supply for clinical trial with full descriptive literature sent free on request.

A. WANDER, Ltd., Manufacturing Chemists,

KAYLENE-OL
for INFLUENZA

TOXAEMIA — REDUCED
CONVALESCENCE — SHORTENED
SECONDARY INFECTIONS—DIMINISHED

The affinity of Kaylene-ol for bacterial toxins renders it particularly valuable in the abdominal type of influenza.

Kaylene-ol detoxicates the saliva and discharges inevitably swallowed when the local lesion is in the nose or throat.

The patient is protected from intestinal poisons generated in food residues, which have been imperfectly digested or retained too long by the debilitated gut.

Samples and "Adsorption" literature obtainable from:—

KAYLENE LIMITED
WATERLOO ROAD, CRICKLEWOOD
LONDON - - - N.W.2

THE TREATMENT OF AN ANAEMIC CONDITION

"The simple inorganic ferrous salts are approximately ten times as effective as any other preparations of iron."—Extract from the article by . . . . , M.D., F.R.C.P., in the PRACTITIONER.

In Iron Jelloids the ferrous carbonate is retained in an unaltered and unalterable state. The action of the air on the iron is prevented and the whole of the iron remains in the easily assimilable form of the subcarbonate. This may easily be demonstrated by simply cutting an Iron Jelloid across. By the light colour of the cross-section the unoxidised condition of the carbonate is at once obvious.

When symptoms indicate that iron treatment is desirable, Iron Jelloids may be prescribed with absolute confidence. Not only is the iron presented in readily assimilable form, but in the experience of many medical men the iron in this form is unusually well-tolerated. Iron Jelloids are favourably reviewed by Medical Journals.

Samples and literature gladly sent free to any Member of the Medical Profession on request.

NATURALLY RICH IN VITAMIN "D"

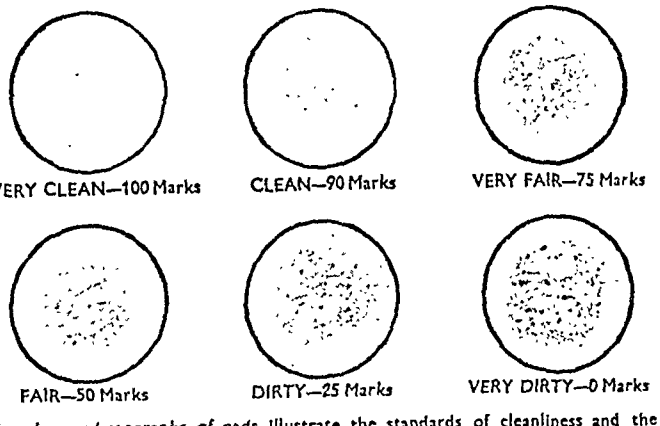
Improving Milk Supplies

New Bonus Scheme for Farmers

CLEAN MILK is an expensive commodity to produce. But only the very best is good enough for COW & GATE, who have therefore always demanded a high quality and special handling of the milk which is the source of their well-known products. Careful laboratory examinations of each churn of milk as it arrives at the factories is insisted on, and every producer is forced to use the special Cow & Gate strainer on the farm. Realizing that educational work and supervision can only be effective up to a point, and that in order to ensure progress beyond this, monetary inducement is necessary, Cow & Gate have now devised a Quality Bonus Scheme.

Starting October 1st, 1932, all milk received has been given marks according to bacterial count, fat content, solid content, and visible sediment, and the producers heading the list are being rewarded by a Bonus on each month's supply of between ½d and 1d per gallon. This has meant as much as £12 a month to a careful farmer. We feel the Profession which is always so interested in the improvement of our milk supplies should know of this step, which we feel is definitely a progressive one.

STANDARDS OF SEDIMENT TESTS



The above photographs of pads illustrate the standards of cleanliness and the corresponding marks awarded in the Bonus Scheme.

TRADE MARK 'EMPIRIN' BRAND
ACETYLSALICYLIC ACID

The brand name 'EMPIRIN' denotes Acetylsalicylic Acid of the highest possible purity. Free from acetic and salicylic acids.

Presented as 'TABLOID' 'EMPIRIN' and in other 'EMPIRIN' products.

Esteemed for accurate dosage and uniform action.

NATIVE RELIGIO-MEDICAL CEREMONIES OF WEST AND SOUTH SIBERIA.—In the scene here reproduced, the shaman and his assistants are assembled. The former, beating his drum, is engaged in applying his supernormal powers by means of supplications and incantations. He has previously discovered which god sent the sickness, by burning the shoulder blade of a sheep and interpreting the signs contained in the resulting cracks. He has learned, too, that a bull must be sacrificed. The animal is killed by a cut in the breast, through which the heart is removed. The trunk is then freed from the skin, which is kept intact and in which the head and legs remain. A long pole is driven through from head to tail, and the head is turned towards the spot where the offended god is supposed to have his dwelling. The flesh is boiled and cut up and pieces of it are offered to the god by being thrown into the air or else burned; the family and friends consume the rest during the shamanising ceremony.

COPYRIGHT

THE "humanisation" of cow's milk involves at least four factors:

1—An adjustment of the ratio of protein to the other constituents of the milk.

2—An increase in carbohydrate to the same sweetness as human milk.

3—An alteration in the physical characters of the caseinogen of cow's milk.

4—A modification of the physical characters of the fat to render this element as easily digestible as the fat of human milk.

■ ■ ■ ■

The first two changes are effected by the removal of a suitable proportion of caseinogen and the addition of carbohydrate. The other modifications are brought about by the addition of a colloid and also by the drying process.

■ ■ ■ ■

"Allenburys" Modified Milk Foods carry these methods into practice; they show that the protein curd of cow's milk may be made to resemble that of human milk in being light, flocculent, and easily digested.

■

This announcement regarding the 'Allenburys' Foods is No. 2 of a series which will be continued.

ON

THE USE OF HYDNOCARPATES AND MORRHUATES INTRADERMALLY IN LUPUS VULGARIS

BY

SIR LEONARD ROGERS, K.C.S.I., M.D., F.R.C.P., F.R.C.S., F.R.S., I.M.S. (RET.)

With a Note on

THE INHIBITORY ACTION OF "ALEPOL" ON THE GROWTH OF TUBERCLE BACILLI IN BESREDKA'S FLUID EGG MEDIUM

BY

PROFESSOR S. L. CUMMINS, C.B., M.D.

AND

CICELY WEATHERALL, M.D., D.P.H.
(From the Tuberculosis Department, Welsh National School of Medicine, Cardiff)

When reporting the beneficial action of soluble preparations of the fatty acids of chaulmoogra and hydnocarpus oils in leprosy in 1916,[1] I expressed the opinion that "the reactions produced by gynocardates in leprous tissues, and the apparent destruction of Hansen's bacillus, raise the very important question as to whether some similar reaction may not be obtained in the case of another human acid-fast bacillus—namely, that of tuberculous disease."

In 1918[2] I reported the use in tuberculous disease of sodium hydnocarpate, and also of sodium morrhuate, which I had made on similar lines from the fatty acids of cod-liver oil, and in the following year[3] I recorded promising results obtained by several observers with injections of sodium morrhuate in various forms of tuberculous disease. In the winter of 1920–1, with the kind help of the Medical Research Council, I tested the action of hydnocarpates and morrhuates in the rapidly fatal acute miliary tuberculosis in the inoculated disease in rabbits and guinea-pigs, with negative results; but I concluded that the possibility of benefit in the much more chronic tuberculous disease of man was not thereby excluded. In 1924, in my fourth Croonian Lecture,[4] I summarized with references the early literature and reported trials of sodium morrhuate in surgical tuberculosis, kindly carried out at my suggestion at the large Carshalton and Fazakerley children's hospitals with somewhat variable results—results which indicated the advisability of further trials. In 1920 E. L. Walker and Marion A. Sweeney[5] reported that the sodium salts or soaps of the lower melting point fatty acids of chaulmoogra oil—consisting mainly of hydnocarpates—which I had found to be most effective in leprosy, had the power of inhibiting the growth of various acid-fast bacilli which will grow beneath the surface of fluid media, including that of avian tuberculosis, in dilutions of 1 in 100,000 to 1 in 1,000,000, but sodium morrhuate had very little such action. It will be seen from the note below that Professor Lyle Cummins has extended this important observation to the human tubercle bacillus, using "alepol," which consists mainly of sodium hydnocarpate. As this preparation can be injected intravenously in considerable doses of a 3 per cent. solution without toxic symptoms, the further trial of hydnocarpates in tuberculous disease appears to be indicated, but it should be used with caution in pulmonary cases as it can produce both general febrile and focal reactions, with softening of the tuberculous lesions.

There is now an extensive literature on the use of these preparations in tuberculosis, but I can only refer here to a very few which have a special bearing on my present subject. Colloidal copper morrhuate, prepared by Dr. Paulo Sebra, has been used extensively in both pulmonary and surgical tuberculosis in South America, and a number of favourable reports have been summarized by Dr. J. Mouzon.[6] These include successful injections into the cold abscesses of gland and bone disease, and also in lupus cases. Cases of lupus treated by injections of "iodomorrhuate" have been reported by O. Blatt and by Jaczewski in Poland,[7] but a reference to Blatt's original paper shows that he used iodine dissolved in potassium iodide mixed with cod-liver oil. In my early work on leprosy in Calcutta I found that extensive nodular lesions were best treated by injecting hydnocarpates directly into them, and this intradermal method has recently been used more extensively in leprosy by C. B. Lara, C. Nicolas, and others[8] with great benefit—confirmed by E. Muir in Calcutta, and by myself in unrecorded cases in this country.

CASE RECORD

I was thus led to try the method of intradermal injections of ester morrhuates and hydnocarpates in the following very chronic case of lupus vulgaris.

A female, aged 42, gave a history of having suffered when a child from "abscesses" on her head and over the base of the spine, and later from ulceration of her face. After various treatments with ointment, etc., by private practitioners and at three hospitals in London, she stated that she underwent the Finsen light therapy at the London Hospital for thirteen years, with nearly 2,000 hours' application in all. This resulted in some temporary improvement, but she abandoned this treatment after seeing "cancer" develop in other cases of lupus. The disease was again spreading when she was sent to consult me in May, 1931. At this time it affected the whole of both cheeks, extended across the forehead and chin, and over both sides of the neck, and had a raised, thickened margin surrounding the whole of the diseased area. There was much scar tissue over her cheeks, while the lower right eyelid had become everted by its contraction. In addition, there was a less active patch of the disease, about two inches square, over her right shoulder. This enabled me to test the effect of the injections first in an unexposed part of the body.

Her progress is a record of steady improvement. I commenced treating the thickened edge of the shoulder lesion by injecting a drop or two of ethyl ester morrhuate intradermally at several neighbouring points at each sitting, so as to produce slightly raised whitish swellings at each point. Different areas were dealt with at each weekly visit. Except for the prick of the needle no material pain or irritation resulted, the temporary swelling at the points of injection rapidly subsided, and within two weeks or so the original thickening of the treated areas showed definite reduction, without any breaking down ever occurring at the sites of the injection. I very soon extended the treatment to the thickened margins on the face and neck, with similar beneficial results. As progress with the morrhuates was somewhat slow I proceeded to use instead the more active ethyl ester hydnocarpate in the form of "moogrol," combined with 4 per cent. creosote as an antiseptic. This also caused very little irritation and no breaking down of the injected areas, while it proved decidedly more effective in quickly reducing the thickening of the treated areas. Moreover, the administration of the hydnocarpates was followed by the appearance of some fresh ulceration in the older, uninjected, central parts of the cheeks. This I regarded as a reaction in the diseased tissues very similar to the swelling and softening of leprous dermal lesions following intravenous or intramuscular injections of the same drug, with, ultimately, very beneficial results in the skin lesions. I therefore returned to the morrhuates for a time, and watched the progress of the reaction in the uninjected lupus lesions with great interest. Only a simple dressing was applied to the ulcers on small strips of linen, such as the patient had long relied on for this purpose. The exposed lupus-diseased tissues in the floors of the ulcers soon came away and the small superficial ulcers healed, leaving much more healthy-looking skin than before the breaking

down had taken place, thus bearing out the analogy with the leprous reactions produced by the hydnocarpates.

It became apparent that, in addition to their local effect, the hydnocarpate injections into the spreading margin of the disease had a generally beneficial effect in the uninjected, long-affected, central portions of the lupus patches. This made me much more hopeful as to the ultimate result. Consequently I continued the treatment with the hydnocarpates alone, and found that the reactions in the central portions became milder, and an increasing number of points could be injected at a sitting, with more rapid improvement. At the end of a year the thickened diseased areas had nearly all disappeared, and the intervals between the injections were increased from one week to two, and later to three weeks. Breaking down of the central areas ceased to take place, with great improvement in the appearance of all the affected skin, while the marginal thickening had nearly all disappeared, so that the edge could no longer be felt, although some redness still remained, except in the central parts, which presented smooth, whitish scar tissue. The shoulder patch has now lost all thickening, and shows only thin scar tissue. Occasional injections are still given, and the patient will be kept under observation to determine if the improvement proves to be permanent or not.

So far the result of this simple method of treatment in a very resistant and extensive case of lupus vulgaris encourages me to recommend its further trial by others with more clinical material than I can command. I may also mention that Dr. T. A. Henry has made a copper hydnocarpate and an iodohydnocarpate. These are now being tried by experts in skin and surgical forms of tuberculosis, but the simple creosoted ester hydnocarpate proved so satisfactory in the above case that I did not have occasion to use them.

INHIBITORY ACTION OF "ALEPOL"

As far as we can ascertain, previous experiments designed to test the inhibitive or bactericidal effects of chemotherapeutical preparations on the tubercle bacillus have been carried out by making surface cultures on fluid media impregnated with the substance under test, or by adding the test substance to nutrient media, which were then solidified and employed as a culture substrate on the surface of which the growth, if any, of the tubercle bacillus could be observed. Examples of these methods are to be found in the works of Möllgaard, Madsen and Mörch, Sweany and Wasick (on sanocrysin), and Walker and Sweeney (on the effects of the hydnocarpates and morrhuates on the growth of acid-fast organisms). The fact that all these methods involve surface growth introduces a possible source of error, since there is a tendency for the tubercle bacillus to heap up its growth vertically as well as to push out laterally, and certain layers of established cultures may be exempt from the action of the chemical substances included in the media.

To avoid this difficulty we decided to work with Besredka's fluid egg medium. A few preliminary experiments with this substance showed that, with the necessary care in its preparation and the use of new-laid eggs, good growth, in the shape of numerous fine balls of culture, could be obtained in the depths of the medium in the course of two or three weeks. A supply of this medium, freshly prepared, was distributed into small Roux bottles —40 c.cm. to each—and the appropriate amount of test substance added, after which the bottles and their contents were sterilized in the autoclave. These Roux bottles, containing sterile Besredka medium, together with varying quantities of the chemical substance under investigation, were now inoculated with equal amounts of an emulsion of *T.B. constantinides*, a human strain of average virulence, one inoculated flask being left without chemical addition as a positive control and one left uninoculated as a negative control. The latter was regarded as important, as a certain amount of precipitation takes place in this medium after some weeks at 37° C., and this might be confused with a fine growth unless a negative control flask were included.

IN VITRO EXPERIMENTS

The substances tested in our first experiment were alepol (B. W. and Co.), a preparation of the sodium salts of a selected fraction of the lower melting point fatty acids of hydnocarpus oil, and an emulsion of cod-liver oil reduced to very fine dispersion in saline. The two latter preparations were supplied to us through the kindness of Sir Leonard Rogers, F.R.S., who informs us that the cod-liver oil emulsion has been prepared by Dr. V. G. Walsh for experiments in the treatment of tuberculosis. Sir Leonard Rogers had not suggested that this emulsion possessed bactericidal properties, nor did this appear probable, but we made use of it so as to exclude any such possibility.

Our results, after incubation of the Roux bottles for thirty-five days, are shown below.

TABLE I

Test Substance	Serial Dilutions			
	1 in 10,000	1 in 100,000	1 in 1 million	1 in 10 million
Alepol	Nil Growth	Nil Growth	Nil Growth	Contamination —
Cod-liver oil ...				

The cod-liver oil was further tested in dilutions of 1 in 100 and 1 in 1,000, a copious growth occurring in both. The positive control flask also contained copious growth, but the negative flask was sterile. To make sure that there were no living tubercle bacilli in the highest dilution of alepol noted as free from macroscopic growth, a volume of 0.5 c.cm. was taken from the 1 in 1,000,000 flask and inoculated into guinea-pigs on January 20th, 1931. At the same time 0.5 c.cm. of the 1 in 10,000 flask of the cod-liver oil emulsion was similarly tested. The cod-liver oil guinea-pig died of generalized tuberculosis on March 18th, 1931, while the animal inoculated from the alepol flask remained in good health until October 9th, 1931, when it was killed, examined, and found free from infection. So far as tubercle bacilli were concerned this experiment appeared conclusive. We found, however, on microscopical examination of our flask cultures, that a non-acid-fast rod, similar in size and certain cultural characters to the tubercle bacillus, which has been a source of trouble in some of our stock cultures during recent years, had appeared in the *constantinides* strain used, and was visible in the positive control contents. We thus felt that the work should be repeated.

In our next experiment, which was carried out on similar lines, the cod-liver oil preparation was left out and only the alepol tested. The results of our second investigation are given in Table II.

TABLE II

Test Substance	Serial Dilutions			
	1 in 10,000	1 in 100,000	1 in 1 million	1 in 10 million
Alepol	Nil	Nil	Nil	Very slight growth

Two positive control flasks showed copious growth and a negative control flask remained sterile. This experiment was carried out with a strain of human tubercle bacillus isolated by Dr. W. H. Tytler, and microscopical examination on the twenty-eighth day of growth, when the flasks were removed from the incubator, showed only acid-fast bacilli. A volume of 0.5 c.cm. of the "end-point" flask, representing a dilution of 1 in 1,000,000 of alepol, was inoculated into a guinea-pig, a similar volume of the fluid from a positive control flask being inoculated into a second guinea-pig on the same date (April 26th, 1931). The animal inoculated from the positive flask died of generalized tuberculosis on June 4th, 1931. The other continued in good health for many months, and was found free from tuberculosis on post-mortem examination.

A test on similar lines with sodium iodohydnocarpate, a new preparation recently sent us by Sir Leonard Rogers, has since been completed. This substance, if a single test is to be accepted as sufficient, does not seem to have the high bacterio-inhibitory powers of alepol, and growth is stopped up to and including a dilution of 1 in 1,000 only. We desire, however, to repeat the investigation of this preparation.

Several similar experiments with alepol, not here described, gave confirmatory results.

IN VIVO EXPERIMENTS

Towards the end of November, 1930, eighteen rabbits were purchased and placed under observation. On December 3rd, 1930, each of these rabbits was infected with an intravenous inoculation of 0.5 c.cm. of an emulsion of a relatively non-virulent strain of human tubercle bacillus isolated by Dr. W. H. Tytler at Cardiff. The dose for each animal, estimated by counting, was 185 millions. Whether as the result of the rather large dose, or of some peculiarity of the batch of rabbits used, our plans were interfered with by a series of early deaths, as described in a previous communication (*Tubercle*, May, 1932). It had been our intention to use twelve rabbits for our experiments and six for controls, but the loss of ten animals made this plan impossible. We therefore grouped our eight surviving rabbits as follows, including two animals for tests with tuberculin for comparison with alepol and finely divided cod-liver oil emulsion.

Tuberculin Group: Rabbits 104 and 109.
Cod-liver Oil Group: Rabbits 96 and 106.
Alepol Group: Rabbits 107 and 97.
Untreated Control Group: Rabbits 99 and 100.

Treatment was started on February 12th, 1931, when the tuberculin rabbits were given 1 c.cm. of 1 per cent. suspension of bacillary emulsion (B. W. and Co.), followed, at weekly intervals, by two doses of 0.7 c.cm. and five doses of 0.5 c.cm. All doses were given intramuscularly into the thigh muscles.

The cod-liver oil rabbits received, at weekly intervals, three successive doses of 0.5 c.cm. of a 10 per cent. suspension of the original emulsion, of which the exact strength was not stated. This dose was raised to 0.6 c.cm. for the last five doses. All these injections were given intravenously, and appeared, at the time, to be well tolerated. The alepol rabbits were given, for the first two doses, 0.5 c.cm. of a 1 per cent. solution in normal saline containing 0.5 per cent. of carbolic acid. The third dose was 0.6 c.cm., and the last five doses 0.7 c.cm. These doses were given intravenously.

On May 26th, 1931, Rabbit No. 96, of the cod-liver oil group, was found dead, and Rabbit No. 106 (the same group) was therefore killed. Both animals were greatly wasted, but in neither was there much evidence of tuberculosis. The remaining six animals were killed on May 28th, 1931.

In order to express our pathological findings in comparative terms we decided to allot "marks" according to the extent and character of the tuberculous lesions in the lungs, kidneys, and other organs respectively. A maximum of ten marks was allowed to each of the latter, making a possible total of 30.

Table of "Marks" for Extent of Lesions

Group	Serial No.	Lungs	Kidneys	Other Organs	Marks
					Per cent.
Tuberculin	104	5	3	2	10 = 33
	109	6	7	0	13 = 43
Cod-liver oil ...	96	0	0	0	0 = 0
	106	5	4	1	10 = 33
Alepol	107	4	2	2	8 = 27
	97	8	5	5	18 = 60
Untreated controls	99	1	3	3	7 = 23
	100	0	1	1	2 = 7

In this series only one rabbit, No. 96 of the cod-liver oil group, escaped without recognizable tuberculous infection. It is to be noted that this animal was the only one of the eight to die spontaneously, and was much wasted. The cause of death and wasting remains obscure, but as both the animals treated with cod-liver oil showed extreme wasting and neither had extensive tuberculosis, it is possible that the dosage of this vitamin-rich preparation was too large, and resulted in toxic effects. The outstanding fact is that both the control rabbits were only very slightly affected by the dose of human tubercle bacilli used. It is quite clear that, even after dosage on such a large scale as to destroy over half the rabbits at what we have described in a previous paper as the "danger period," the surviving animals tended to overcome to a varying extent the implanted human tuberculous lesions —and this quite apart from the treatments given.

CONCLUSIONS

1. The experiments *in vitro* prove that alepol possesses marked growth-inhibiting properties when introduced into a fluid medium suitable for "deep" cultures of tubercle bacilli.

2. The fact that in two experiments guinea-pigs survived after inoculation with tubercle cultures in Besredka egg medium containing alepol in a strength of 1 in 1,000,000 only, suggests that this substance may have bactericidal as well as growth-inhibiting properties for tubercle bacilli.

3. Our experiments in the treatment of rabbits artificially infected with human tubercle bacilli proved inconclusive, owing to the fact that the untreated control animals exhibited a well-marked toleration for the culture used. The results, however, do not suggest that the alepol had any specific curative effect. It is to be noted that the tuberculous lesions found at necropsy were, as usual, almost completely avascular, a fact which might be expected to nullify the effects of a bactericidal or growth-inhibiting substance introduced into the blood stream.

4. The marked anti-bacterial properties of alepol, as demonstrated by our tests *in vitro*, suggest that this substance may yet be found to play a useful part in the sterilization of the tuberculous pleural effusions which often accompany artificial pneumothorax therapy, or in

the treatment of other closed spaces, such as cold abscesses, containing tubercle-infected fluids.

This work has been greatly facilitated through a grant from the Medical Research Council, for which we desire to express our best thanks.

AETIOLOGY OF HODGKIN'S DISEASE
WITH SPECIAL REFERENCE TO B. TUBERCULOSIS AVIS

BY

C. E. VAN ROOYEN, M.B., CH.B.

ASSISTANT, BACTERIOLOGY DEPARTMENT, UNIVERSITY OF EDINBURGH

The relation of Hodgkin's disease to tuberculosis has been the subject of extensive inquiry, and many workers, such as Sternberg (1898), Ewing (1927), and others, have repeatedly drawn attention to the similarity of tissue changes produced in both conditions. Opinion, however, is divided on the incidence of tuberculosis in patients suffering from lymphadenoma. Ewing says that "tuberculosis follows Hodgkin's disease like a shadow"; Lemon (1924) reports, to the contrary, that out of 191 cases of Hodgkin's disease under observation in the Mayo Clinic only eight showed evidence of tuberculosis. The latter worker further states that out of twenty-six cases of the disease in which the mediastinal glands were involved there was definite evidence of tuberculosis in only one.

Infective agents other than the tubercle bacillus, such as the diphtheroid organism (Bunting and Yates, 1913), certain moniliae (Dias, 1918) and amoebae (Kofoid, Swezy, and Boyers, 1922), have been described in Hodgkin's disease, but such work has lacked confirmation. Stewart and Dobson (1924) attempted to reproduce the disease in monkeys (*rhesus* and bonnet), but without results. Twort in 1930 published the results of six years' research into the causation of the condition, and arrived at the conclusion that the disease was probably of neoplastic origin, since he was unable to isolate any one organism with constancy or to reproduce the disease in laboratory animals with pathological material.

More recently American workers have advanced two fresh views on the aetiology of the condition. Medlar (1931) maintains that the disease is one primarily affecting the bone marrow, for which he proposes the name "megakaryoblastoma" in view of the particular type of cell involved. L'Esperance (1929–31) claims to have reproduced Hodgkin's disease in birds and "treated" guinea-pigs, from whose tissues she recovered the avian tubercle bacillus. This investigator therefore states that Hodgkin's disease is produced by infection with *B. tuberculosis avis*. This view has been further elaborated by Utz and Keatinge (1932), who claim to have treated successfully several cases of lymphadenoma by the use of serums obtained from chickens previously immunized with lymphadenomatous tissue. I have investigated the claims of L'Esperance by the inoculation of chickens and other laboratory animals with material obtained at biopsy from three cases clinically and histologically characteristic of Hodgkin's disease, and also with material removed at necropsy from three other cases of the disease, two of which showed mediastinal involvement.

The following brief extracts of case and post-mortem notes describe the subjects from which material was obtained.

CASE HISTORIES

1. *Case of Professor Fraser's.*—A male, aged 52, had swelling in left axilla of eleven months' duration, with later ulceration and secondary infection lasting three months. There was slight enlargement of the inguinal and infraclavicular glands, with no evidence of mediastinal involvement. Ten per cent. eosinophils were present. Histological diagnosis: Hodgkin's disease.

2. *Case of Dr. Comrie's.*—A female, aged 28, had a swelling of the glands of the neck for eight months, with later involvement of abdominal glands and spleen. These changes were accompanied by extensive bronzing of the skin and intolerable itching. Throughout her illness a fever conforming to the Pel-Ebstein type was present, and the blood picture showed an eosinophilia. At post-mortem the cervical, mediastinal, bronchial, and abdominal para-aortic glands were grossly enlarged, together with slight enlargement of the lymph nodes of the lesser omentum. The spleen was enlarged to about three times its normal size, and contained numerous nodules throughout. The heart, liver, and lungs also showed involvement with lymphadenomatous tissue.

3. *Case of Professor D. Murray Lyon's.*—A male, aged 46 complained of vague symptoms of general illness lasting three months, with loss of appetite and weight, diarrhoea, colic, and dyspnoea. Temperature reaction of the Pel-Ebstein type was present, accompanied by enlargement of liver and spleen. At post-mortem there was considerable enlargement of para-aortic, abdominal, and mediastinal lymph glands, with commencing enlargement of the cervical and inguinal groups. The bone marrow revealed red patches suggestive of erythroblastic reaction, and microscopically proliferation of bone marrow cells affecting the red cell series was found to be present.

4. *Case of Professor Bramwell's.*—A male, aged 27, gave a three months' history of loss of weight and appetite, accompanied by distension of the abdomen and bronzing of the skin. On admission the patient was found to have an enlarged spleen, dullness over the apex of the right lobe, with crepitations and vesicular breathing. Pel-Ebstein type of fever was present. Red blood cells were 4,200,000 per c.mm., and white cells 3,800: differential count was normal, and haemoglobin 70 per cent. Post-mortem revealed typical lymphadenoma of spleen, liver, and para-aortic and cervical glands. Brown atrophy of the heart. No evidence of tuberculosis demonstrable.

5. *Case of Professor Fraser's.*—A female, aged 31, first noticed lumps on her neck two years before examination, initially confined to the left side, but later involving the right. These painless swellings rapidly increased in size, and later gave rise to pressure symptoms in that region. There was no palpable enlargement of spleen, liver, or lymph glands in inguinal or axillary regions. An intermittent fever accompanied her illness. Red blood cells were 4,540,000 per c.mm., and white cells 9,200: polymorphs, 75 per cent.; lymphocytes, small, 11 per cent.; large, 9 per cent.; eosinophils, 4 per cent.; transitionals 1 per cent. Haemoglobin was 70 per cent.; colour index, 0.08. Histological diagnosis: Hodgkin's disease. Deep *x*-ray therapy and subcutaneous injections of Coley's fluid over the affected area were employed, which resulted in marked diminution in the size of the glands and considerable general improvement.

6. *Case of Dr. Chalmers Watson's.*—A schoolboy, aged 8, gave a five years' history of progressive enlargement of submental, supraclavicular, axillary, and inguinal glands, and of the spleen. Increasing weakness and cachexia, severe secondary anaemia, accompanied by cardiac haemic murmurs, commencing integumentary dryness and pigmentation were present. During the last two years patient exhibited a typical Pel-Ebstein pyrexia. The histological diagnosis, clinical manifestations, course of the disease, and reaction to deep *x*-ray therapy have shown this case to be almost a textbook picture of the disease.

EXPERIMENTAL WORK

Enlarged lymph glands removed at biopsy, together with liver, spleen, and bone marrow obtained in necropsy, were examined for the presence of avian tubercle bacilli by direct attempts at cultivation on Dorset's egg media, but no such organisms were isolated. It is of interest, however, to state that in both Cases 1 and 6 a small, typical, Gram-positive, aerobic diphtheroid organism was isolated after about ten days' incubation. Both strains subsequently proved to be non-

pathogenic to laboratory animals, and so further investigations were discontinued. About 300 histological sections of affected glands and viscera were stained for acid-fast organisms, but none were found.

Animal Inoculation

Four bantam chickens and four street pigeons were inoculated both intravenously (through the wing vein) and intraperitoneally with 2 to 3 c.cm. of a dense emulsion of affected material, comprising enlarged lymph glands, spleen, and bone marrow. Animals were kept under observation for a period of seven to ten months, but no signs of illness were noticed. Two chickens which had been inoculated with emulsions of spleen and lymph gland by the two routes were examined post mortem ten months later, but found to be perfectly healthy.

Grafting Experiments

Five healthy chickens (three buff orpingtons and two white leghorns) were used for these experiments. With strict aseptic precautions small fragments of an enlarged lymph gland (removed at biopsy by Professor Fraser, from Case 5) were implanted into the birds as follows. (1) *Extraperitoneally.* (2) *Intraperitoneally.* (3) *Intrahepatically:* This was carried out by making a V-shaped incision into the free margin of the left lobe of the liver, and inserting into this a wedge-shaped portion of gland, which was then secured by means of catgut sutures. (4) *Into shaft of femur:* This was done after the manner of an intramedullary graft, and performed by exposing the femur, removing a U-shaped fragment of bone with the aid of bone-nibbling forceps, and then inserting small fragments of lymphadenomatous tissue into the proximal and distal ends of the medullary canal. (5) *Intramuscularly:* Implantation was in the pectoral muscles. All five birds made a good recovery from the operation, and at the end of a week appeared to be in good health.

Animal No. 1 died after three months, succumbing to accidental injury. Necropsy revealed that the attempted graft had undergone necrosis and subsequent extrusion into the superficial tissues, while the surrounding tissues showed extensive fibrosis and cicatricial contracture, presumably in the nature of a reaction towards a foreign body. No evidence of tuberculous ulceration or caseation was to be found in the underlying tissues, peritoneum, or viscera. Animal No. 3 was killed after six months and the site of the attempted graft examined both macroscopically and microscopically, but no changes indicative of tuberculosis were evident and no bacterial growth was obtained on culture. The remaining animals are still under observation, and appear to be healthy after seven months.

DISCUSSION

In the experiments described above no evidence of infection with *B. tuberculosis avis* was found in material taken from six accurately diagnosed cases of Hodgkin's disease.

Cases of human infection due to the avian tubercle bacillus have already been described by several European workers. Löwenstein (1913) obtained the organism from cases of pulmonary, renal, and dermal tuberculosis. Rabinowitsch (1907) succeeded in isolating the organism from the spleen of a case of generalized miliary tuberculosis, and Janscó and Elfer (1910) also demonstrated organisms of a similar type in the mesenteric glands of a child. It would thus appear that the occurrence of human infection by the avian tubercle bacillus has been proved, and isolation of the causative organisms seems to have been achieved by the usual well-recognized methods. With reference to the claims made by L'Esperance, I have not only failed to produce tuberculosis in chickens by inoculation with lymphadenomatous material, but I have also been unable to demonstrate the presence of avian tuberculosis in affected material, either by direct cultural methods or by examination of a large number of stained histological preparations.

It is noteworthy that in the literature of the cases of human tuberculosis due to avian tubercle bacillus there is no mention that the clinical manifestations of these cases in any way differed from the syndrome produced by infection with the ordinary human or bovine types. Indeed, it is questionable whether the true nature of the causative agent would have been determined had a special search not been made for it.

The feeble pathogenicity of the avian tubercle bacillus to the guinea-pig and its more pronounced effect on the rabbit are well-recognized characteristics (Medlar, 1931) that cannot be lost sight of when one also remembers that the non-pathogenicity of lymphadenomatous material to rabbits and guinea-pigs is a fact of wide acceptance. A notable exception to this is found in the results obtained by M. H. Gordon and co-workers of the Rose Research on Lymphadenoma (1932), who have demonstrated that the intracerebral injection of lymphadenomatous tissue into rabbits is followed by ataxia, muscular spasms, and paralysis. Such effects are not produced, however, by the injection of leukaemic, sarcomatous, and carcinomatous tissue. L'Esperance nevertheless claims to have reproduced avian tuberculosis in birds by the injection of lymphadenomatous material into them, without having simultaneously done so in rabbits. The same worker's claim to have reproduced Hodgkin's disease in guinea-pigs which had previously been inoculated with killed cultures of *B. tuberculosis hominis* is also unconvincing.

It should also be pointed out that, according to Griffith (1930), under domestic conditions poultry exposed to infection readily develop tuberculosis, frequently following the ingestion of contaminated food. Organs most commonly involved are the intestine, liver, and bone marrow, but the writer has been unable to reproduce avian tuberculosis by the introduction of lymphadenomatous tissue directly into these areas.

SUMMARY AND CONCLUSION

Pathological material obtained from six accurately diagnosed cases of Hodgkin's disease have been examined by direct cultural methods for the presence of the avian tubercle bacillus, and histological sections examined for acid-fast organisms, but both with negative results. Tissue emulsions have proved to be non-infective to rabbits, guinea-pigs, pigeons, and chickens on intravenous, intraperitoneal, and intramuscular administration. Attempts to graft lymphadenomatous material obtained from an acute case of Hodgkin's disease into the bone marrow, peritoneum, liver, and muscles of chickens have likewise failed.

No evidence of *B. tuberculosis avis* can be found in cases of Hodgkin's disease.

I wish to express my thanks to the many members of the University teaching staff from whom assistance was obtained, in particular Professor J. S. Fraser, Mr. Eric Meikie, Dr. J. Davidson, and Professor T. J. Mackie. The cost of animal experiments has been defrayed by a grant received from the Moray Fund of Edinburgh University.

ATYPICAL HODGKIN'S DISEASE

BY

E. G. B. CALVERT, M.D., M.R.C.P.

AND

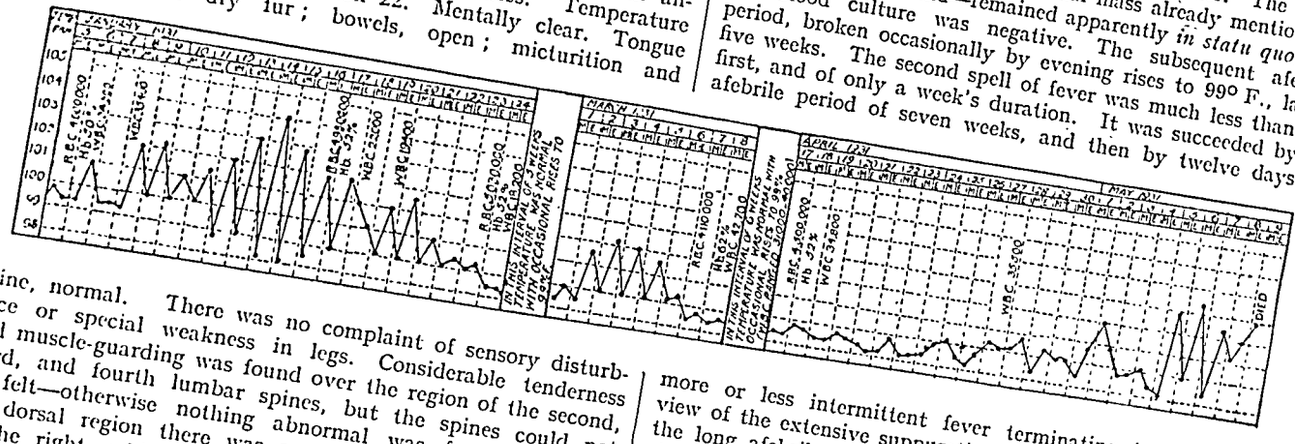
HAROLD H. SANGUINETTI, M.A., M.D.

The following case of Hodgkin's disease seems worthy of publication on account of certain difficulties in diagnosis due to unusual signs and symptoms and because of uncommon post-mortem findings.

CASE RECORD

History.—A married woman, V.T., aged 31, was admitted to the National Temperance Hospital on January 5th, 1931. Twenty-one months previously she had, for no apparent reason, been suddenly seized for the first time with a severe lancinating pain in the lumbar region. Aspirin gave relief in one and a half hours. Since then backache, varying in intensity, had been present daily. She had gradually lost strength, and shortly before admission had lost weight rapidly —"almost four stone in about as many months." There was nothing of interest in the previous history—no injury to the spine, no pneumococcal, typhoid, staphylococcal, or other infection. Family history was of no interest.

On admission the patient was very ill-looking, with anæmia, manifest wasting, and great weakness. Temperature 99.8° F., pulse 94, respiration 22. Mentally clear. Tongue whitish, with dry fur; bowels, open; micturition and



urine, normal. There was no complaint of sensory disturbance or special weakness in legs. Considerable tenderness and muscle-guarding was found over the region of the second, third, and fourth lumbar spines, but the spines could not be felt—otherwise nothing abnormal was found here. In the dorsal region there was a pronounced scoliosis, convex to the right, which apparently had not been noticed until admission to hospital. It was thought that the deformity was compensatory to distortion from vertebral destruction in the mid-lumbar region. For about an inch or two to the right and left of the middle line, and extending roughly from 3 inches above to 1 inch below the umbilicus, was felt an ill-defined mass, tender and seemingly firm in consistency. Bowel distension and inability of the patient to relax properly made palpation very imperfect. Though there was a possibility of this being glandular in nature no glandular enlargement was discovered. Liver, spleen, heart, lungs, nervous system, mediastinum, skin, fauces, and gums gave no sign of disease. A few shotty lymphatic glands were noticed in both groins and one moderately enlarged gland at the root of the right side of the neck. Pelvic examination showed "tenderness on pressure high up in the right vaginal fornix, and on moving the cervix. No mass felt." (Mr. D. Denham Pinnock.)

Pathological and X-Ray Examination.—Microscopical examination of the excised lymphatic gland in the neck showed extensive fibrosis obliterating glandular structure, but areas of lymphocytes remaining intermingled with numerous endothelial cells, some of these being so large as to suggest mononuclear giant cells. Structure not definitely lymphomatous, but might represent the fibrous stage of a lymphadenomatous gland." (H. H. S.) The *x*-ray reports are as follows:

a) Lumbar and lumbo-sacral regions: "Much absorption of body of third lumbar vertebra. Some absorption along superior surface of fourth lumbar vertebra. Probably a tuberculous lesion."

(*b*) Thorax: "Some thickening of the hilar shadows on each side. Lung tissue clear. Diaphragm moves well. No radiological evidence of tuberculosis."

The blood Wassermann reaction was negative, while the blood culture, at the height of the fever (January 15th, 1931) was also negative.

Blood Counts.—Twelve counts were done (H. H. S.) in hospital. Space precludes giving these in detail; the main features of most are shown on the temperature chart. In the differential count the percentages of white corpuscles were as follows:

Polymorphs, 80–91 (average 85); lymphocytes, 6–20 (average 12); large mononuclears, 1–5 (average 3); eosinophils, 0–3 (average 0.5); basophils, 0–1 (average 0.4); myelocytes, 0–2 (average 0.25).

It will be noted that the secondary anæmia that was in progress remained more or less stationary to the end, also that the degree of leucocytosis did not correspond with the degree of fever, the highest counts, indeed, being obtained when the temperature was normal or nearly so.

Fever.—As will be seen from the chart there were, in hospital, three bouts of fever. The first was the most marked, and lasted three weeks. High and intermittent during the second week, the fever disappeared at the end of the third week in a surprising and unaccountable manner. The spinal defect and the indefinite abdominal mass already mentioned—the only lesions found—remained apparently *in statu quo*, and the blood culture was negative. The subsequent afebrile period, broken occasionally by evening rises to 99° F., lasted five weeks. The second spell of fever was much less than the first, and of only a week's duration. It was succeeded by an afebrile period of seven weeks, and then by twelve days of more or less intermittent fever terminating in death. In view of the extensive suppurative changes found post mortem the long afebrile periods (mentioned again later) are of considerable interest, especially after the fierce initial bout of fever and the seemingly moribund condition of the patient. The pulse rate remained throughout in the region of 80–90, except when the temperature was high, when it went up to 100–115, and, just before death, to 132.

Appearance and Nutrition.—The changes undergone by the patient in this respect were remarkable. On admission a pale, emaciated woman, obviously suffering great pain, she began to gain in strength and put on weight rapidly as soon as she reached the afebrile stage. Even the short febrile period in March did not greatly impede her progress, and from April 13th to 17th she actually had a menstrual period, the first for eight months. The subsequent rapid downhill progress, terminating in death, was therefore both surprising and disappointing.

Post-Mortem Examination

Nothing abnormal was found in the cranial cavity or brain. In the thorax there were present greatly enlarged mediastinal and peribronchial glands, while in the right lung two nodules could be felt, one in the upper and the other in the lower lobe, the larger being the size of a walnut. Some nodules, not easily palpable, were present in the left lung. On section the nodules were seen to project beyond the level of the surrounding lung tissue, and looked like secondary deposits of new growth. No abnormality was found in the alimentary tract. There was a chain of greatly enlarged lymphatic glands extending from both inguinal regions along the iliac arteries and aorta up to the pancreas and spleen. Those on the left side were suppurating, and there was a large abscess in front and on the left side of the third and fourth lumbar vertebrae, burrowing into and destroying the left psoas muscle and eroding the bodies of the vertebrae, so that a finger could be passed into the spinal canal, although the

abscess was outside the theca. The affected third and fourth vertebrae had undergone considerable rotation, being twisted so that their spines pointed to the left instead of posteriorly—the reason for their not being felt on clinical examination. The liver was normal, and macroscopically there appeared to be only moderate simple hypertrophy of the spleen. Nothing abnormal was detected in kidneys, uterus, and ovaries.

Microscopical Appearances.—The following tissues were examined: abdominal and thoracic lymphatic glands, periosteum and fibro-cartilage from the lumbar vertebrae, and one of the nodules from the lung. The general histological plan was the same in all, so that on cursory examination one might easily mistake a section of the lung nodule for one of a lymphatic gland. In the lymphatic gland the lymphocytes are diminished and their place partly taken by proliferating endothelial cells, including many characteristic mono- and multi-nuclear giant cells with centrally placed nuclei—the so-called Sternberg giant cells. The reticulum is much hypertrophied, and large strands replace the lymphocytes, some of which remain as islands surrounded by fibrous tissue. Where suppuration has occurred polymorph cells abound in the pus and in the abscess wall. Granulomatous changes involve the periosteum of the invaded vertebrae and the intervertebral disk. In the lung nodule, except at the periphery, the pulmonary alveolar structure has been obliterated. The tissue is very vascular and blood has been extravasated. There is, for the most part, nothing particular about the granulomatous structure except the presence of many neutrophilic polymorph leucocytes, while in one or two areas a considerable number of giant cells of the Langhans type are present. A few such cells are the centres of islands of tissue having the appearance of a tubercle, others are interspersed with the cells of the granuloma. There is no sign of caseation.

Hirschfeld,[1] describing similar cells present in lymphadenoma, regards them as tuberculous, but the presence of other cells showing an apparent transition from the Sternberg type of giant cell to the Langhans type suggests that in this case these cells constitute a rather unusual form of granulomatous change, a view strengthened by the absence of signs of tuberculous disease elsewhere in the lung.

DISCUSSION

The signs and symptoms exhibited by the patient were: anaemia, with marked and rapid emaciation; severe pain in the back and sides, with lateral curvature of the spine and tenderness over the lumbar vertebrae; attacks of remittent or intermittent fever separated by lengthy afebrile, or nearly afebrile, periods, and a high leucocytosis of inflammatory type. The patient's extraordinarily rapid improvement during the afebrile period should also be regarded as a symptom.

Reference to Ziegler's excellent monograph[2] shows that all these symptoms, with the possible exception of the spinal curvature, may be met with in cases of Hodgkin's disease, yet one would submit that not all of them are commonly present in, or generally recognized as associated with, the disorder. Mention is here made of the severe pains and the leucocytosis, and although the existence of the inflammatory type of leucocytosis in the latter stages of lymphadenoma is now more generally recognized, figures as high as 240,000 have been reported (Schur). Of bone involvement and pain, Ziegler[2] says: "Involvements of bone are relatively common in Hodgkin's disease; generally they do not betray themselves clinically"; and, again: "In connexion with bone involvement severe pains can arise." The same author's masked, or typhoid, form of the disease, in which the retroperitoneal glands are affected almost exclusively, corresponds very closely with this case, for from the results of *x*-ray examination one may reasonably assume that the involvement of the mediastinal glands and lungs was a late manifestation. However, some of the usual symptoms of these masked cases, such as oedema of the feet and abdominal wall, and diarrhoea, were absent, also the leucopenia of this type of lymphadenoma was replaced by a leucocytosis. Finally, there was no clinical enlargement of the spleen. The rapid but highly deceptive improvement in the patient's general condition—so apt to encourage belief in any form of treatment—is worth further consideration. "These patients, brought desperately low in the fever periods, can actually swell up—that is, put on flesh—during the afebrile periods, though anatomically the disease continues to spread" (Ziegler[2]). This reaction is diagnostically useful only in the presence of enlarged glands of doubtful nature. This feature of the disease appears not to be widely recognized.

The post-mortem and microscopical findings exhibit further points of interest, differentiating this case from the average case of Hodgkin's disease. Thus the formation of pus in the iliac glands and the large abscess surrounding the bodies of the affected vertebrae and extending into the left psoas muscle is quite an unusual occurrence in lymphadenoma, as is also the associated marked erosion of the bodies of the third and fourth lumbar vertebrae with consequent spinal curvature. However, involvement of the vertebrae is by no means so uncommon as Ziegler would lead one to suppose. Thus, examining the lumbar vertebral bodies in twenty-two cases, Professor H. M. Turnbull found them implicated in eight (36.4 per cent.), and examination of the dorsal vertebrae in two cases revealed similar involvement in each. In all cases the areas of disease were macroscopic in the sawn-through vertebrae. In our case the changes were more profound. Commenting on the case described by Drs. Hare and Lepper,[3] Dr. Parkes Weber suggests direct extension from glands to the vertebral periosteum, a view also expressed by Professor Turnbull.[4] The extraordinarily firm adhesion of some of the glands to the vertebrae in our case supports this view.

The breaking down of the glands and the formation of the perivertebral abscess may be ascribed to a secondary infection. It is unfortunate that this probability was not explored when the post-mortem examination was made. The polymorph pus in the walls of the abscesses certainly suggests a secondary invading organism. Professor Turnbull, whom we desire to thank for his kindly help, states that "while firm caseation is common in Hodgkin's granuloma, we have never at the London Hospital seen an abscess in an uncomplicated case of Hodgkin's disease." The absence of obvious enlargement of liver and spleen is unusual in this type of case, and it is regretted that these organs were not examined microscopically. As to the lung, Ziegler's[2] estimate of involvement in 8 per cent. of cases probably exaggerates the frequency. The absence of pulmonary symptoms would be remarkable were it not that a mild bronchitis, easily overlooked in the presence of more serious symptoms, is usually the only manifestation of the granulomatous changes.

The diagnostic difficulties in the case were, in the first place, due to the absence of any mass ascribable with certainty to enlargement of lymphatic glands, to the leucocytosis of an inflammatory type, but above all to evidence of disease of the vertebral column accompanied by severe pain. As has been stated, the *x*-ray report suggested tuberculous disease of the spine, but the age of the patient, the high fever, and the inflammatory type of leucocytosis suggested as a more likely diagnosis infective osteomyelitis of the spine, though no focus of infection was found, and no history of such or of a general infection was obtained. According to H. W. Carson[5] deformity is rare in this disease, but lancinating pain unrelieved by rest—such as occurred in this case—is characteristic, whereas in Pott's disease pain is usually relieved by rest. The same writer refers to the frequency of abscess in osteomyelitis, but in our case abscess formation was a post-mortem finding. Carson obtained in blood culture a pure growth of *Staphylococcus aureus* in all his cases, whereas blood

culture in our case was negative. Nevertheless, as suppurative changes are unknown in Hodgkin's disease, apart from secondary infection, the osteomyelitic nature of the infection taking part in the extensive erosion of the vertebral bodies and development of the abscess may be regarded as the correct explanation.

The case here reported is further proof of the extraordinary difficulties that may have to be overcome in order to arrive at the correct diagnosis of Hodgkin's disease.

THE PHYSIOLOGICAL AND CLINICAL RESULTS OF DIVISION OF THE VAS DEFERENS*

BY

A. CLIFFORD MORSON, O.B.E., F.R.C.S.

SURGEON TO THE HAMPSTEAD GENERAL HOSPITAL, AND ST. PETER'S HOSPITAL FOR URINARY DISEASES, ETC.

The vas deferens, or spermatic duct, is the tube which carries the mature spermatozoon from the testicle to the seminal vesicle. It is lined by ciliated epithelium, and the lumen in comparison to the thickness of the wall of this duct is extremely small. The vas deferens has very little contractile power, the reason for which is obvious when it is remembered that the spermatozoon is mobile and is assisted towards its destination by cilia. It is only when it has entered the seminal vesicle that muscular effort is required to urge it further forward on its final journey. There must be some correlation between the vesicles, when they are fully distended with spermatozoa, and the migration of these sperm cells from the seat of their development. The capacity of the seminal vesicle is limited, and thus some control must be exercised over the number of spermatozoa which may travel in any given time along the vas deferens. It is pure surmise how this comes about, but in all likelihood a distended vesicle has an inhibitory effect upon the movements of the cells from the testicle. Coitus has but an indirect relation to these activities.

When the vas deferens is divided or ligated it is necessary to consider the effect upon the testicle, the seminal vesicle, and the prostate gland. As regards the latter, it should be obvious that no change, either physiological or anatomical, will take place, and yet in the days before prostatectomy was introduced it was a common practice to divide both vasa in the belief that the operation would result in a decrease in the size of the enlarged prostate. It is probable that this procedure was intended as a substitute for castration, which was the treatment in vogue during the nineteenth century. The removal of the testicle was discarded on account of the mental complications which it produced, but though it had no effect upon the adenomatous growth of the gland, the latter eventually underwent atrophy, due, of course, to disuse.

Division of the vas deferens *per se* has no effect upon either the function or size of the prostate gland. The quantity of the secretion is unaltered. It thus comes about that the man who has had both vasa divided is unaware of any change in the act of coitus. The quantity of fluid ejaculated is normal, but there are no spermatozoa present. With the knowledge that the vesiculae seminales merely function as reservoirs for the mature spermatozoa it is clear that any interference with the flow of cells into these small pouches must lead to their gradual shrinkage and complete atrophy. This is exactly what happens after a dissolution of the continuity of the vasa deferentia. The vesicles, at first palpable through the wall of the rectum, slowly shrivel until they are no longer to be felt by rectal examination.

A much more difficult study is the effect of duct division upon the testicle. There is one definite negative finding—namely, that there is no change in the shape and size of the gland. On the other hand, little is known as to the life history of the spermatozoon when it is imprisoned within the tubules of the epididymis. One can only surmise that the adult cell dies of inanition, unemployed and unwanted. Is the process of development of the sperm cell interfered with by the inability of its mature relatives to escape from the nest and migrate, as nature intends them to? Here again, in another but less important form, is the problem of the unemployed and its effect upon control of the birth of the unwanted. The urge to further formation of spermatozoa must remain, even after division of the vas, so long as sexual desire persists. One can visualize the overcrowding of the tubules of the epididymis with adult cells and the final squeezing out of existence of those that have not reached maturity. The final phase, in all probability, is the testicle's impotence to produce any sperm cells at all.

Such, in brief, are the physiological results of division or ligation of the vasa deferentia. Equally interesting and instructive are the clinical results of this simple surgical procedure.

OPERATIVE TECHNIQUE AND COMPLICATIONS

The operation can be carried out by any medical practitioner with a knowledge of minor surgery, but it must be stressed that this operation, if not performed efficiently, may lead to serious complications.

By far the easiest method of exposing the vas is as follows:

After the skin of the scrotum has been sterilized with iodine, picric acid, or methyl violet the vas is felt for immediately below the external abdominal ring. On the right side it is easily isolated with finger and thumb from the other constituents of the cord, but the left one is not so readily picked out on account of the multiplicity of veins which surround it. As soon as the duct is firmly gripped and fixed an incision is made in the scrotal skin between the operator's finger and thumb. With a pair of toothed forceps the vas is held while the tissues surrounding it are dissected away. It is then cut across and each end crushed between artery forceps. Should the surgeon desire to inject the vesiculae seminales with an antiseptic or sclerosing solution in order to prevent subsequent vesiculitis the proximal end of the vas must not be crushed until the injection has been made. The procedure is: the proximal end of the cut vas is lightly held with forceps while a blunted hypodermic needle is passed down its lumen. (A sharp-pointed needle is found to catch in the wall of the duct and prevent the flow of fluid along the correct channel.) As soon as the surgeon is satisfied that the needle is in the right position 4 c.cm. of 1 in 10 carbolic acid—or any other antiseptic and sclerosing solution which may be preferred—is injected by means of a glass syringe. By this technique the vesiculae seminales are sterilized, and, if the correct solution is used, also sclerosed. The divided ends of the vas are now pushed back into the scrotum and the skin wound sutured with catgut.

The complications which may arise from division of the vas are, in the main, the result of errors of technique. Thus, failure to maintain perfect asepsis will lead to scrotal cellulitis and the surrounding of the testicle by a hard mass, which has been mistaken for epididymo-orchitis. Again, particularly on the left side, a vein may be punctured during dissection and the error not recognized. The result is the formation of a scrotal haematoma.

* A post-graduate lecture delivered at the Hampstead General Hospital, November 9th, 1932.

...stly, a thickened spermatic vein can be divided in ...stake for the vas, and when or if orchitis follows, the ...g surgeon proclaims the uselessness of duct division ... a prophylactic measure!

In those cases where the vas has been divided for the ...vention of orchitis, and infection of the seminal ...esicles has subsequently occurred, the following signs ...d symptoms may be observed:

The patient complains of aching in the groin, and has a ...ight rise of temperature. Palpation of the tissues in the ...g... of the external abdominal ring will reveal a swelling tender on pressure, which may be no larger than a pea or as big as a bantam's egg. The lump is due to the formation of a localized induration of the tissues around the proximal end of the cut vas. So acute was the onset of the symptoms and so sudden the appearance of the swelling at the lower end of the groin in one patient, that the condition was mistaken for a strangulated hernia. These symptoms rarely last longer than a few days unless an abscess forms. When the latter takes place resolution quickly occurs following evacuation of the pus. The transitory constitutional disturbance produced by a small abscess at the point of division of the vas is as nothing compared with pus formation in the testicle. The inflamed vesicle can be felt through the wall of the rectum as a thickened cord projecting upwards and outwards from the upper limit of the prostatic bed. Tenderness is an uncertain sign.

It is clear from the observations which have been made on the mode of spread of infection from the bladder neck and prostatic urethra to the testicle that the effect of division of the vas has determined, once and for all, the channel by means of which bacteria reach the latter. This channel must be either the lumen of the vas or lymphatics within its wall, for the technique of division has consisted solely of breaking the continuity of the duct. Perivasal lymphatics are not interfered with. Proof of the correctness of this observation lies in the fact that infection from the prostatic urethra, the vesicles, or the prostatic bed, following removal of the gland, terminates at the point of division of the vas deferens.

General Indications

It is now necessary to consider the indications for this operation as a means of checking the spread of infection to the testicles from the bladder and urethra.

Following removal of the prostate for simple enlargement or any other disease, no technique has yet been devised which prevents some degree of infection in the prostatic bed. So long as this infection exists there is the danger of bacteria spreading from the sump of serum and urine collected in this space, firstly to the seminal vesicles, and thence, via the vas deferens, to the testicle. Thus in all cases of prostatectomy an essential part of the operative technique must be division of the vasa deferentia. The importance to the patient of safeguarding his testicle from infection after he has safely weathered the storm of prostatic disease and the operation of prostatectomy is brought home to the surgeon, who, having failed to divide the vasa, is faced with the problem of treating recurrent attacks of orchitis when he has flattered himself his patient is rid of all his bladder troubles. In urinary tuberculosis when the bladder becomes involved, subsequent complications may be prostatitis, vesiculitis, and urethritis. These organs are affected through the passage of tubercle bacilli in the urine. Once this has occurred there is the further menace of involvement of the external genitalia. It is therefore a wise step, when the prostate and seminal vesicles have been discovered to be tuberculous, to limit the further genital spread of the disease by division of both vasa deferentia. Likewise in genital as opposed to genito-urinary tuberculosis, immediately epididymitis occurs there must be a dissolution of the continuity of the sperm duct to avoid involvement of the accessory sexual organs.

THE ROLE OF MINERALS AND VITAMINS IN GROWTH AND RESISTANCE TO INFECTION*

BY

ALAN BROWN, M.D., F.R.C.P.(C.)

AND

FREDERICK F. TISDALL, M.D., F.R.C.P.(C.)

(From the Department of Paediatrics, University of Toronto, and the Hospital for Sick Children)

During recent years more and more attention has been devoted by the medical profession to the role of minerals and vitamins in human nutrition. In the present paper we wish to review some of the work which is being done in this field at the Hospital for Sick Children, Toronto. This work has been undertaken, not with the object of discovering methods for the cure of various disease conditions, but in an attempt to determine the value and importance of these dietary factors for normal development and resistance against disease. There are at least ten inorganic elements which are absolutely essential for life—namely, sodium, potassium, calcium, magnesium, phosphorus, chlorine, sulphur, iodine, iron, and copper. From the standpoint of the practising physician we are fortunate in having to watch the supply of only three of these elements, because any reasonable diet will furnish the other seven elements in adequate amounts. The supply of the three elements calcium, iron, and iodine, however, should not be left to chance.

Essentials in Diet

Although calcium is the fourth most widely distributed element in the earth's crust, its occurrence in foods is quite limited. Our two chief sources of calcium are milk and leafy vegetables. As regards the child's diet, it may be stated that it is absolutely impossible to furnish an adequate amount of calcium unless liberal amounts of milk are given. This can readily be demonstrated by the following facts. A diet comparable to that found in many uninformed families, composed of rolled oats and bread-and-butter for breakfast, beef, potatoes, carrots, cabbage, and rice for dinner, potatoes, bread-and-butter, and honey or jam for supper, with four ounces of fluid milk to go on the rolled oats and rice, supplies only 0.3 gram of calcium. Yet the average 10-year-old child requires approximately one gram of calcium each day (Rose). The additional 0.7 gram of calcium required can be furnished by one pint of milk per day, or a total milk intake of 24 ounces per day. If all the milk is omitted, the amount of calcium furnished by the remaining portion of the diet is reduced to the absurdly low figure of 0.17 gram. It is thus evident that we depend mostly on milk to supply the large calcium needs of the growing child.

Iron is another mineral element that is not so widely distributed in food that its supply can be left to chance (Sherman). This is particularly true with the small infant, whose diet consists largely of milk and cereal, both of which foods are deficient in iron. Egg yolk, liver, and spinach and other green vegetables are our richest sources of iron in foods. The supply of iodine is probably an easy matter in Great Britain, owing to proximity to the sea. With us, however, in the centre of the North American continent, the iodine content of the water and the food is extremely low. We depend largely on iodized salt to furnish this element.

* Read in the Section of Diseases of Children at the Centenary Meeting of the British Medical Association, London, 1932.

A lack of vitamin A in the diet results in a keratinization of the epithelial cells. Our chief supply of vitamin A is butter-fat, egg yolk, carrots, spinach, and cod-liver oil. A lack of vitamin B_1 results in peripheral neuritis or beri-beri, while a lack of vitamin B_2 results in pellagra and possibly certain skin diseases. Vitamins B_1 and B_2 are found largely in yeast, wheat germ, milk, liver, egg yolk, and spinach and other leafy vegetables. Vitamin C, the antiscorbutic vitamin, is found in oranges, lemons, tomatoes, cabbage, and other fruits and vegetables. It is readily destroyed by heat in the presence of oxygen. Vitamin D, the antirachitic vitamin, is not found in ordinary foods, with the exception of small amounts in egg yolk and summer milk. Fish oil, such as cod-liver oil, is our most concentrated natural source. In recent years vitamin D has been produced by the irradiation of ergosterol. Vitamin E, the reproductive vitamin, is found in wheat germ, lettuce, and other leafy foods.

GROWTH AND RESISTANCE IN ANIMALS

In addition to the well-recognized deficiency diseases produced by a lack of vitamins and minerals, we have studied the importance of these food elements on growth and resistance to infection. Each one of these vitamins and minerals is essential for life, so it is only reasonable to expect that if any one of them is omitted from the diet the individual will eventually lose weight and die.

In animal experiments this has been found to be the case. In our rats fed on a normal diet the average gain in weight over a period of six weeks was 100 grams. When calcium was reduced from the optimal figure of 0.612 per cent. to 0.26 per cent. the average gain over the same period was 80 grams. In regard to phosphorus, we found that if this element was reduced from the optimal level of 0.45 per cent. to 0.24 per cent. the animals, instead of making the normal gain of 100 grams in six weeks, gained only 66 grams. With a lack of iron* the rate of gain was reduced 33 per cent. over a period of eleven weeks. Some of the vitamins have been spoken of as the growth-promoting vitamins, but a glance at Fig. 1 shows that a reduction of any one of the vitamins

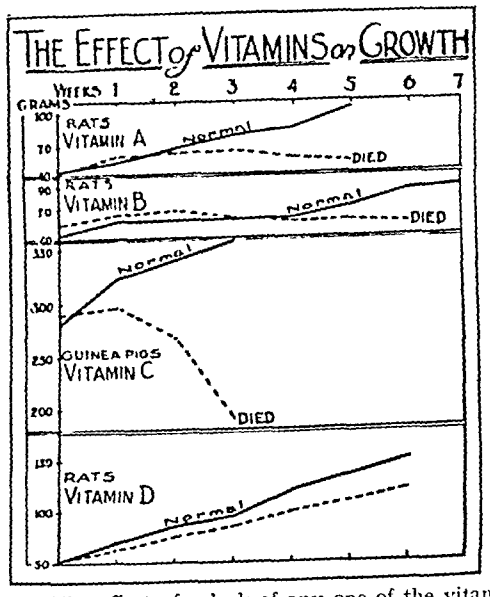

FIG. 1.—The effect of a lack of any one of the vitamins on growth.

(with the exception of E) results in loss of weight. The influence of vitamin A in maintaining a normal condition of the epithelial cells of the respiratory tract and normal resistance against infection is so well recognized that this vitamin is frequently called the anti-infective vitamin. By a method devised in our laboratories by Dr. Elizabeth Chant Robertson the effect of a lack of the vitamin B complex and of vitamin D has been studied. The procedure consisted in feeding the rat the desired deficient diet for a period of two to four weeks, and then giving by mouth a measured amount of an organism pathogenic for the rat, known as *Salmonella muriotitis*. The animals were then watched for a period of four weeks, and the number of survivors noted. Blood cultures were made from the heart blood of all animals shortly after death, and the very occasional animal which did not show a positive culture was discarded as having died from some other cause. The results given in Tables I and II show

TABLE I.—*Effect of the Vitamin B Complex on Resistance to Infection*

Vitamin B Deficient Diet			Vitamin B Deficient Diet with 6 per cent. Dried Brewers' Yeast Added		
Total Number of Rats	Number of Survivors	Percentage of Survivors	Total Number of Rats	Number of Survivors	Percentage of Survivors
73	12	16	68	47	69

TABLE II.—*Effect of Vitamin D on Resistance to Infection*

375	106	28	364	201	55

that a lack of the vitamin B complex and of vitamin D lowers the resistance of rats to infection.

VITAMIN D

As already mentioned, vitamin D is not present in perceptible amounts in ordinary table foods, with the exception of small and variable amounts in egg yolk and summer milk. Our tests show that eggs procured in the open market in Toronto in the month of March contained as little as two Steenbock vitamin D units per egg yolk. (One drachm of standard cod-liver oil contains 46 Steenbock vitamin D units.) As paediatricians, we see extremely severe rickets in the winter months in infants receiving as much as one quart of milk per day. This makes it plainly evident that the human race does not depend on ordinary foods for its source of vitamin D. As shown in recent years, we depend on the ultra-violet rays of sunshine and skyshine to produce this vitamin in our bodies. We have studied the variations in the antirachitic value of sunshine in Toronto over a period of some years, and found that the antirachitic potency of summer sunshine was approximately eight times as great as winter sunshine. The chief deciding factor in this change in potency is the altitude of the sun above the horizon. It was found that when the sun was below 35 degrees it produced only a slight effect as compared with the effect produced when above 35 degrees. In Toronto, even in the middle of the day, the sun is always below 35 degrees for four months of the year, whereas in the latitude of London this occurs for five months of the year, and in the latitude of Glasgow for six months of the year. This means that in Great Britain the sun has only a slight antirachitic effect for five to six months of the year. This, combined with modern methods of living indoors, and the smoke pall over the large cities, makes it plainly evident that unless some special means are taken the average individual will not receive an amount of vitamin D commensurate with optimal health.

The use of cod-liver oil and other vitamin D products obtained through the drug stores has increased greatly in recent years, with a resultant improvement in the health of the rising generation. We have been accustomed, possibly, to think only of the antirachitic effect

* The effect of an iron deficiency in lowering resistance against infection in humans has been strikingly demonstrated by Dr. Helen Mackay.

of vitamin D; the recent work of May Mellanby and others has shown conclusively the value of vitamin D in the prevention of dental caries. It is inconceivable that a vitamin so essential for life in the early years should not be essential throughout childhood and adult life, although in a decreasing amount. Taking all these facts into consideration, we felt that if an additional supply of vitamin D could be made available to the public, which would be obtained by it at no additional cost, and by no effort on its part, we would be doing something well worth while. Accordingly, we incorporated vitamin D, in the form of irradiated ergosterol dissolved in corn oil, in the shortening used in making bread, so that each 24-ounce loaf contained the vitamin D equivalent of 3 drachms of cod-liver oil. This bread is now being produced in some fifteen cities in Canada and some sixty cities in the United States.

USE OF SPECIAL CEREAL

It has been stated that cereal grains furnish from 30 to 60 per cent. of the calories of the average diet. Most cereal products as used to-day are highly refined and contain only a small amount of minerals, and are almost devoid of vitamins. This, combined with the rather extensive use of refined sugars, which are quite devoid of both minerals and vitamins, makes it evident that a very severe strain is placed on the remaining portion of the diet to furnish an adequate supply of both vitamins and minerals. In view of these facts, we felt that if an infant or breakfast cereal could be devised which, in addition to supplying calories, would furnish minerals and vitamins in appreciable amounts, it should prove to be a valuable addition to the average dietary. However, on account of the general preference for refined and finely milled cereals, it was felt that in order to be generally used the cereal should resemble those widely used products in taste, appearance, non-laxative effect, and keeping qualities. Accordingly a cereal has been devised that fulfils these requirements, and has the following composition: wheatmeal (farina), 53 per cent.; oatmeal, 18 per cent.; corn meal, 10 per cent.; wheat germ, 15 per cent.; bone meal, 2 per cent.; dried brewers' yeast, 1 per cent.; alfalfa, 1 per cent.

The wheat germ is used on account of its high protein, mineral, and vitamin content. It contains a moderate amount of vitamin A and is exceptionally rich in vitamins B_1 and B_2, and is the most concentrated known source of vitamin E. Dried brewers' yeast supplies vitamins B_1 and B_2, in addition to the amount already furnished by the wheat germ. Alfalfa is added on account of its high vitamin A and mineral content. We have found that 1 per cent. machine-dried alfalfa furnishes sufficient vitamin A for the cure of xerophthalmia in rats. The iron content of alfalfa is more than 130 mg. per hundred grams, which is ten times the amount found in egg yolk, one of our most concentrated sources of iron in commonly used foods. The bone meal, which is an odourless, tasteless white powder, is used on account of its high calcium and iron content. This cereal mixture has been used exclusively for the past two years in the Hospital for Sick Children, Toronto, and is also extensively used throughout the United States and Canada. In the infant wards, from the standpoint of a laxative, no difference was noted from the results obtained with the refined and finely milled cereals ordinarily used. The palatability of the product was evidenced by its being eaten with the same avidity as the ordinary cereal, not only by the infants, but also by the older children.

A study was made of the rate of growth of children given daily 2 ounces (dry weight) of this cereal mixture in place of ordinary cereals. Some twenty-four children in all were taken, and were divided into two groups, one receiving ordinary cereals in a well-balanced diet, and the other the special cereal mixture in the same well-balanced diet. The children were kept under identical conditions and weighed at weekly intervals over a period of ten weeks. At the end of ten weeks the groups were changed, and the ones on ordinary cereals now received the special cereal mixture and the ones on the special cereal mixture received ordinary cereals. Their weights were observed over an additional ten-week period. The results obtained are shown graphically in Fig. 2. It

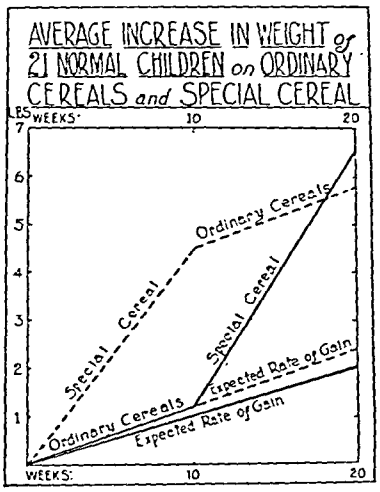

FIG. 2.—Comparison of the increase in weight of children fed on the special cereal and ordinary cereals.

is to be noted that on the special cereal mixture the children gained four to five times their expected rate, in contrast with the average rate of gain obtained while on ordinary cereals.

CONCLUSIONS

We believe that more care should be taken to ensure an adequate supply of both minerals and vitamins in the diet. The importance of these food essentials in the maintenance of normal growth and resistance against infection is not as widely recognized as it should be. Unfortunately we do not know the exact requirements of these food essentials, nor do we know the exact amounts furnished by many foods. We do know, however, that, owing to the ease with which we can obtain purified carbohydrates, we are apt to suffer from insufficient amounts of minerals and vitamins, and, in occasional cases, of proteins. Nevertheless one can go a long way towards overcoming the deficiencies so frequently encountered in the average diet by building up our meals around five essential articles of food—namely, milk, to supply calcium and protein; meat, to supply protein; eggs, to supply protein, vitamins, and iron; and vegetables and fruit, to supply minerals and vitamins. The remaining calories required can be furnished readily by the refined cereal and sugar products.

After many years of practical experience we are prepared to say that a more widespread observance of these few simple fundamental principles will go a long way towards improving the health of the community, and will materially assist us in reaching that goal which is the keynote of preventive medicine—namely, optimal health.

THE VALUE OF CAESAREAN SECTION IN PRE-ECLAMPTIC TOXAEMIA

BY

MARGARET M. BASDEN, M.D.LOND.
F.R.C.S.ENG., F.C.O.G.

OBSTETRIC SURGEON, MOTHERS' HOSPITAL, CLAPTON; SURGEON, SOUTH LONDON HOSPITAL FOR WOMEN

The object of this communication is to suggest that, although Caesarean section should never play anything but a small part in the treatment of pre-eclamptic toxaemia, it might, nevertheless, be used with advantage more frequently in the most serious cases. In my experience, the high mortality which has been shown to follow Caesarean section when eclampsia has actually supervened[1] does not occur when the operation is performed in the pre-eclamptic stage. The following is a short series of thirty cases of pre-eclamptic toxaemia treated by Caesarean section with no maternal deaths and no subsequent development of eclampsia. I have done my best to include all my cases so treated, but it is possible that one or two may have been overlooked, owing to difficulty in tracing the earlier records. I can state definitely, however, that I have never had a maternal death in a patient treated by Caesarean section for pre-eclamptic toxaemia, and the same applies in cases of Caesarean section performed for other reasons, but in which a mild degree of toxaemia was present, too slight to include in this series.

Caesarean section for toxaemia does not condemn the patient to delivery by this method in subsequent pregnancies. Since it is from eclampsia that the patient dies, and not from pre-eclamptic toxaemia, I seldom operate unless eclampsia appears to be so imminent that there is no time to induce labour. My usual practice in severe cases is to keep the patient on water only, or water, glucose, and lemonade, for twenty-four hours. The response to this treatment is generally satisfactory, but if at the end of that time there is only a slight improvement, I induce labour, while if the condition is the same, or worse, I perform Caesarean section. I should have operated sooner in some of the following cases had they come under my care earlier. I have not found that toxaemic patients stand the operation less well than others, and I am forced to the conclusion that the risk of operative procedure in this condition has been overestimated.

Vaginal Caesarean section was performed in one case; in all the others the classical operation was carried out. The anaesthetic employed was usually ether, sometimes preceded by ethyl chloride on an open mask. I should prefer spinal anaesthesia, or gas and oxygen, but, since the operation need not take more than a quarter of an hour, I do not think the choice of the anaesthetic is of very great importance. This may prove a practical point in an emergency operation.

Eclampsia following Induction

That induction, even when followed by the immediate onset of labour, is too slow a method to be relied upon to prevent eclampsia in severe cases is illustrated by the following examples.

Case 1.—Mrs. A., a primipara, was under my care for her confinement. When thirty-eight weeks pregnant, her husband a doctor, reported a trace of albumin for the first time. He blood pressure, which on a previous occasion had been 13 was 150. There was practically no oedema, and she felt qui well. As she had a slightly contracted pelvis, and inductio had already been considered for this reason, it was decide to induce labour, although neither the toxaemia nor the pelv contraction alone seemed sufficient to indicate this. She we

Case No.	Date of Admission	Age	Para	Duration of Pregnancy (weeks)	Condition on Admission and till Operation	Reason for Operation and Date	Date of Discharge and Result	
							To Mother	To Ch
1	September 19th, 1924	25	1	40	Blood pressure 145; much oedema of abdominal wall and legs. No albumin, although this had been present in antenatal department	September 24th. Despite treatment oedema increased; blood pressure rose to 170, and urine was loaded with albumin. Labour was induced with a stomach tube, but on following day blood pressure was 175, and albumin had still further increased. [illegible] very slowly [illegible] ogress of labour owing to disproportion. General condition getting worse. Temperature 101.2°	October 13th. Febrile puerperium. Finally did well	Good
2	May 1st, 1925	26	1	40	In labour. Membranes ruptured; heavy cloud of albumin. Blood pressure 152. (Oedema of face, feet, and abdominal wall had been noted four days earlier in antenatal department, but notes do not say whether this was present on admission)		July 2nd. Febrile puerperium; Finally did well	Good
3	November 22nd, 1925	30	1	40	Admitted with "show." No pains; no toxic symptoms. Following day developed very severe headache, nausea; trace of albumin. Blood pressure 160. Drug induction failed	December 4th. Extended breech which would not descend with good pains. Toxic symptoms were still present on December 2nd, but were getting less. Condition on day of operation is not stated in notes	December 23rd. Good	Goo
4	June 4th, 1926	39	2	40	Oedema of feet, legs, and abdominal wall. Blood pressure 130. Passing very little urine; trace of albumin. All symptoms improved, but she later relapsed	June 22nd. Almost complete anuria; what there was was loaded with albumin. Very marked oedema; blood pressure 148. Very anxious for a living child; twins had been diagnosed and it was feared they would succumb to the toxaemia	July 23rd. Good	Tri al w
5	April 1st, 1927	25	1	32	Very marked oedema. Urine loaded with albumin; had been vomiting. Blood pressure 170	April 2nd. Worse, despite being on water only. Urine nearly solid on boiling. Blood pressure 184	April 28th. Good	Go
6	May 13th, 1927	23	1	40	Much oedema and albuminuria. Blood pressure 160	May 14th. After water only for 24 hours, urine was nearly solid on boiling; only 16 oz. passed. Blood pressure still 160	Good	Go
7	May 27rd, 1927	29	1	? 36	Oedema of feet and legs; much albumin. Blood pressure 160. Temporary improvement followed by relapse despite medical treatment	May 29th. Blood pressure 190. Much albumin; headache	June 18th. Good	Go
8	September 30th, 1927	38	1	38	Much albumin; oedema of feet. Headache and eye symptoms. Blood pressure 144. Temporary improvement under treatment, then oedema, albumin, and blood pressure increased. On October 6th blood pressure was 164	October 7th. Tending to get worse despite treatment, although on actual day of operation there was improvement, and blood pressure was 128	October 26th Good	G
9	November 4th, 1927	24	1	[illegible]	Looked ill. Puffiness of face; very marked oedema of vulva and much oedema of legs. Much albumin. Blood pressure 140	November 4th. Risk of eclampsia supervening seemed too great to allow time for medical treatment	November 24th. Good	G
10	January 20th, 1928	24	1	34	Much albumin and oedema. Blood pressure 140. After water only for 24 hours and magnesium sulphate, albumin was the same, oedema less. Blood pressure 170. [illegible] same; following day, [illegible] he vomited. [illegible] was Blood pressure 150	January 22nd. Failure of response to medical treatment. Fear that eclampsia might supervene during induction	February 11th Good	G

TABLE (*continued*)

Case No.	Date of Admission	Age	Para	Duration of Pregnancy (weeks)	Condition on Admission and till Operation	*Reason for Operation and Date*	Date of Discharge and Result	
							To Mother	To Child
11	July 4th, 1928	25	1	36	Blood pressure 172 (which rose to 180) and albuminuria. Under treatment blood pressure dropped to 135 and albumin disappeared			
12	Re-admitted August 11th, 1928				When re-admitted blood pressure was 210. Eye symptoms present; albuminuria. Attempt to induce labour by bougies, followed by "intensive" drug treatment, unsuccessful. Toxaemic symptoms improved temporarily, then began to increase again	August 23th. Recurrence of toxaemic symptoms after temporary improvement. Failure to induce labour	September 17th. Good	Stillborn
13	September 29th, 1928	24	1	? 38	Vomiting; slight jaundice. Albuminuria and oedema. Blood pressure 115	September 30th. After strict medical treatment condition became worse. Blood pressure 118. Restlessness, headache, epigastric pain, and blurred vision. Albumin and bile in urine. Marked oedema	October 26th Good; febrile puerperium, but developed active tuberculosis	Twins; both did well
14	February 8th, 1929	25	1	40	Much albumin. Blood pressure 185	February 9th. After 24 hours on water only blood pressure was 180	March 2nd. Eventually good; convalescence delayed by bronchitis	Good
15	April 5th, 1929	27	1	33	Albuminuria; much oedema. Blood pressure 152	April 6th. After 24 hours' medical treatment blood pressure 172	June 10th. Eventually good; convalescence delayed by phlebitis	Good
16	May 13th, 1929	27	1	? 38	Much oedema and albumin. Blood pressure 165. (In the ante-natal department a high blood pressure and oedema had preceded the albuminuria)	May 14th. After 24 hours' medical treatment blood pressure was 150. (She was apparently either worse, or no better, but the notes of this and of the two preceding cases are deficient)	June 11th. Good	Good
17	April 4th, 1930	27	2	34	Much albumin; blood pressure 165. Despite treatment blood pressure rose next day to 200, dropping to 190. Albumin less.	April 6th. Blood pressure 195. Vomiting; face puffy. Worse, despite medical treatment	April 23. Eventually good; convalescence delayed by bronchitis	Good
18	July 7th, 1930	36	1	38	Blood pressure 178. Nausea, headache, and vomiting. Much albumin and oedema of legs	July 8th. After water and barley sugar only for 24 hours blood pressure was 175; passing very little urine. The patient had already been advised Caesarean section for contracted pelvis	July 23th. Good	Good
19	August 28th, 1930	30	1	40	Much oedema, headache, and vomiting. Blood pressure 135. No albumin on admission, but this appeared next day	September 21st. Temporary improvement under medical treatment, followed by relapse. Blood pressure now 170; much albumin	October 10th. Good	Good
20	October 17th, 1930	27	1	40	Oedema and headache; albumin absent or trace only. Blood pressure 150. Admitted for drug induction. Oedema and high blood pressure (170) had preceded albuminuria in ante-natal department	October 19th. No result from drug induction. Trace of albumin; headache. Blood pressure 170. Getting worse, despite medical treatment	November 8th. Good	Good
21	October 19th, 1930	25	1	35-38	? In labour. Abdominal pain and vomiting. Oedema of feet and legs; blood pressure 150. There is no note as to condition of urine on admission, but there had been a faint trace of albumin in ante-natal department, preceded by oedema and high blood pressure	October 20th (12.30 a.m.). Blood pressure rose to 200 after admission, and eclampsia seemed imminent	November 8th. Good	Good
22	January 23th, 1931	21	1	30	Blood pressure 195. Oedema; much albumin (oedema, headaches, and high blood pressure had preceded albuminuria in ante-natal department). Two attempts to induce labour by insertion of bag failed	February 3rd. (Vaginal Caesarean section.) Persistent high blood pressure and albu-	February 23rd. Good	Stillborn
23	January 30th, 1931	20	1	34	Oedema of feet and much albumin. Blood pressure 180. After 24 hours on water only blood pressure was 150	February 2nd. Blood pressure rose again to 170. Severe headache; oedema increasing	February 20th. Good	Good
24	March 20th, 1931	28	3	34	Severe headaches and eye symptoms. Blood pressure 150. Much albumin. (Had albuminuria in ante-natal department for more than three weeks, despite medical treatment)	March 20th. Had albuminuria and high blood pressure with both previous pregnancies; the first was induced at 6½ months. The present operation was performed both to prevent onset of eclampsia and to sterilize	May 8th. Good. The long convalescence was due to delayed healing of wound	Died day after birth
25	April 6th, 1931	31	2	—	Albuminuria. Oedema of legs and feet and enormous oedema of vulva; two pints of fluid let out by tapping. Blood pressure 145	April 12th. Chief toxaemic symptom was great oedema of vulva, which reappeared after tapping	May 4th. Good	Twins; both did well
26	June 23rd, 1931	26	2	26	Much albumin; oedema. Blood pressure 190. After water only for 24 hours blood pressure was 210; highest reading was 220, fell before operation to 210	June 27th. To prevent eclampsia and to sterilize. She had severe toxaemia with previous child, which was induced at 25th week, but which lived and did well	July 8th. Good	Died
27	September 21st, 1931	24	1	32	Oedema; trace of albumin. Blood pressure 145	October 4th. Getting worse despite treatment. Drug induction failed. Blood pressure 180; headache and eye symptoms	October 23th. Good	Twins (dead; born alive
28	November 18th, 1931	34	5	34	Oedema; cloud of albumin Blood pressure 235. (Previous pregnancies said to have been uncomplicated)	November 18th. Ten hours later blood pressure 220, despite water, glucose, etc., only. Fear of impending eclampsia	Jan. 2nd. Good. Prolonged convalescence owing to phlebitis	Good
29	April 1st, 1932	—	1	38	Much oedema and albumin. Blood pressure 165	April 4th. Improved at first on water only; blood pressure fell to 120, then rose to 150. Headache	April 25th. Good	Good
30	November 1st, 1932	25	1	40	Oedema of legs, hands, and face. Blood pressure 132. Heavy cloud of albumin. (*Trace of albumin noted in ante-natal department four days previously*)	November 5th. Albuminuria gradually disappeared under strict medical treatment, and the oedema diminished, but the blood pressure continued to rise, and on day of operation it was 174	November 25th. Good	Good
31	December 9th, 1932	25	2	40	Blood pressure 172. Much albumin. Had had trace of albumin in ante-natal department on three separate occasions, the first being in September. It always disappeared on dieting, and the blood pressure varied from 110 to 140	December 9th. She was admitted for operation the same day, both to prevent eclampsia and because she had had toxaemia in her previous pregnancy and a stillborn child. She was kept on water only until the operation, but the blood pressure continued to rise slightly (to 175) and the urine became almost solid with albumin on boiling	Good	Good

into the nursing home, and her urine was then found to be albumin-free. Later in the day labour was induced by rupturing the membranes.[2] Pains started about two hours later, but eleven hours after the membranes had been ruptured she had a fit, and the urine was found to be almost solid with albumin.

Case 2.—Mrs. W. was admitted into a maternity home for treatment for severe toxaemia. The urine was loaded with albumin, her legs were very oedematous, and her blood pressure was between 180 and 190. After she had been in bed on a restricted diet the oedema diminished and the albumin almost disappeared; the blood pressure remained the same. About five days after admission the oedema began to increase again, the blood pressure remaining as before. The doctor then decided to induce labour; the operation was very successful, labour starting in four hours. The child was born twenty-four hours later, but by then the mother had had an eclamptic fit, and I had been asked to see her in consultation.

In both cases the mother and child did well and the induction probably diminished the severity of the disease. It gave time, however, for the relatively safe pre-eclamptic condition to pass over into the very dangerous one of eclampsia, although in both cases there was a minimum of delay between the induction of labour and the birth of the child. The second case illustrates the prognostic value of the blood pressure compared with other symptoms, and this is the symptom on which I chiefly rely in estimating the severity of the case. I have also found that when the high blood pressure and oedema appear before the albuminuria the toxaemia is particularly apt to be severe. This happened four times in my series.

Figures are not available to show what percentage of cases of pre-eclamptic toxaemia develop eclampsia, but it has recently been suggested that 6.4 per cent. of late pregnancy toxaemia cases develop this condition.[3] It is reasonable to assume that the percentage, when only the most severe cases are considered, would be higher, and therefore that some of the cases in this series would certainly have developed eclampsia but for the operation.

It has been argued that this method of treatment is contrary to the interests of the child, but in my experience the child is more likely to die as the result of prolonged toxaemia in the mother than from prematurity, and I sometimes use this as an argument to the parents in advising the operation. The figures in this series show that the actual foetal mortality was 17.1, six children having died of the thirty-five that were born. This included three sets of twins, of whom one set died, and one of triplets. Five out of the thirty mothers, or 16.6 per cent., lost their children, and twenty-three of them, or 76.6 per cent., were primiparae.

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

A CASE OF POST-VACCINAL ENCEPHALITIS

The following brief account of post-vaccinal encephalitis occurring in an adult and resulting in recovery seems worthy of record.

Miss N. B., a robust, healthy girl, 19 years of age, was primarily vaccinated with fresh glycerinated calf lymph on November 15th, 1932. Two vaccination marks were made on the left calf.

On November 28th the patient attended surgery, complaining of malaise, lassitude, and diffuse headache. On examination she had normal pock-marks with no inflammatory areolae. The same evening all symptoms were accentuated and vomiting occurred once. The headache had become occipital; there was no stiffness of the neck; and all reflexes were normal, except for an indefinite Babinski reflex on the left. Temperature 101° F., pulse 80, respiration 24.

Early on November 29th, after a night of alternating restlessness and drowsiness with occasional vomiting, she was apathetic and answered questions briefly. Stiffness of the neck was marked, with no retraction. Pupils and retinae were normal, except for slight lateral nystagmus. The lower abdominal reflexes, the left knee-jerk, and both ankle-jerks were absent. The upper abdominal reflexes and right knee-jerk were diminished. There were bilateral Babinski and Kernig reflexes (left ++, right +). At midday the patient was comatose, with urinary incontinence. Lumbar puncture produced 32 c.cm. of clear fluid, and 10 c.cm. of anti-meningococcal serum was substituted intrathecally. The leucocyte count showed 18,125 cells per c.mm., 80 per cent. being polymorphonuclears. At midnight the patient was unconscious, with Cheyne-Stokes respiration. She was then given an intravenous transfusion of 30 c.cm. citrated blood from her mother, who had been vaccinated twenty years previously, and 23 c.cm. of cerebro-spinal fluid was withdrawn by lumbar puncture. One hour after transfusion generalized skeletal spasm occurred, which ceased after subcutaneous injection of adrenaline.

Early on November 30th the patient was still comatose and incontinent of urine and faeces, but Cheyne-Stokes breathing had ceased. Consciousness gradually returned, and towards evening she became restless. At midnight 30 c.cm. of serum from a Group IV donor, who had been vaccinated three and a half years previously, was given intravenously, and 20 c.cm. of cerebro-spinal fluid was withdrawn by lumbar puncture.

On December 1st the comatose state gave way to a lethargic state. Sphincter control was restored, but occasional enuresis persisted. During December 2nd, 3rd, and 4th the following reflexes were still absent: left upper and both lower abdominal, both knee- and ankle-jerks. Plantar responses extensor.

On December 14th all abdominal reflexes and both knee-jerks were present; the left plantar response was still extensor and the right flexor. Neither pain nor paresis was observed throughout. Further recovery was uneventful.

EXTRACT FROM CEREBRO-SPINAL FLUID EXAMINATION
(*November 29th, 1932*)

Culture—sterile.
Cells—233 per c.mm. 1/3 small lymphocytes.
1/3 polymorphonuclears.
1/3 large endothelial.
Globulin—increased.
Protein—45 mg. per 100 c.cm.
Sugar—57.7 mg. per 100 c.cm.

JULES F. REY.

Bognor Regis.

INTESTINAL POLYPUS AND INTUSSUSCEPTION

It may be of some interest to record the following case.

The patient, a boy aged 6, was sent to me last summer with a history of vague abdominal pains with occasional vomiting. The bowels were somewhat constipated, with intermittent passage of bright red blood. On examination the general condition was fairly good. The abdomen was somewhat distended and distinctly tender over the appendicular area. Nothing abnormal was made out on rectal examination. A barium meal examination did not help in any way. A diagnosis of appendicitis was made. It was thought that an intestinal polypus might also be present.

At operation the appendix, which was subacutely inflamed, was removed. A search was then made along the large intestine for a polypus, and about the middle of the transverse colon a rounded mass, about three-quarters of an inch in diameter, was found. It felt like a piece of faeces, and on attempting to milk it in a downward direction I noticed that an invagina-

tion commenced at a point about two inches proximal to the mass. The bowel at this moment became spastic, and held the lump in this position. It became evident that one was dealing with a polypoid tumour with a long pedicle. A small opening was made over the tumour, and a polypus, with its two-inch pedicle and base, was excised. Recovery was uninterrupted.

I think the invagination seen during the operation proves conclusively that a polypus of the intestine is a definite cause of intussusception.

Aberdeen. ANDREW FOWLER, F.R.C.S.Ed.

GENERAL PERITONITIS FOLLOWING RUPTURE OF A PERINEPHRIC ABSCESS

The case reported below is of interest because of the rather unusual sequence of events.

A youth, aged 19, was admitted to the Walton Hospital, Liverpool, with general peritonitis. He was thin and emaciated, and obviously moribund. He had a history of sudden pain in the left hypochondrium, which had occurred seven days previously. He had refused to see a doctor until the day before admission. At the age of 6 he fell from the rear of a lorry and sustained a fractured pelvis and a rupture of the urethra. Since then he had not passed urine normally.

Just above the pubis was a fistula, which barely admitted the point of a probe, and from which foul-smelling urine was oozing. He had refused operative relief.

Post Mortem. — There were the usual appearances of generalized peritoneal infection, but no appendicitis. Both ureters were dilated; the right kidney showed pyelitis, and the left several abscesses, one of which had ruptured and given rise to a perirenal abscess, which in turn had ruptured into and infected the general peritoneal cavity. The bladder showed acute cystitis. The prostatic portion of the urethra was dilated, and contained five or six faceted calculi. Beyond this there was complete urethral obstruction.

I am indebted to Dr. T. B. Davie for the post-mortem findings, and to Dr. MacWilliam and Mr. A. Wilson for permission to publish the details.

SURGICAL EMPHYSEMA AS A COMPLICATION OF MEASLES

In the textbooks surgical emphysema in connexion with measles finds no place, and the literature would appear to contain but few cases.[1] The combined condition is therefore of such rarity that the following case justifies record.

A boy, aged 7, was admitted to the Coventry City Hospital on July 8th, 1932, the tenth day of illness. The case presented a generalized morbilliform eruption and typical catarrhal manifestations, with cough and hoarseness; the temperature was 100.8° F., pulse 148, and respirations 28. Examination of the chest revealed a patchy bronchopneumonia in both lungs. Surgical emphysema was already evident, the initial appearances being in the infraclavicular and supraclavicular regions, with the sign of "crackling" on palpation of those parts. The resultant ballooning was bilateral and symmetrical.

On the day following admission the air infiltration of the subcutaneous tissues quickly extended. The face, the neck, the whole of the chest wall, the abdominal wall, and the scrotum were now markedly involved; the arms and forearms were affected in small degree, but the lower extremities remained unaffected. No signs of pneumothorax were evident. On the succeeding day—the twelfth day of illness—the escape of air into the tissues was such that tension and mechanical respiratory embarrassment were severe, and cyanosis became marked. Treatment included the insertion in appropriate places of hollow needles, which penetrated only to a subcutaneous level; through them much of the air found egress, confirming the subcutaneous location of the air. The patient's general condition remained substantially unaltered until eight days later, when improvement was noted. Thereafter the bronchopneumonia resolved, the emphysematous condition subsided, and the case advanced to complete recovery twenty-one days after admission to hospital.

The following are possible theoretical explanations of the occurrence of surgical emphysema in such a case: (*a*) Breaking down of a pneumonic patch on the lung surface, involving adherent visceral and parietal pleurae and allowing air to escape from pulmonary vesicles via the mediastinum and the superior aperture of the thorax to the cellular and subcutaneous tissues of the neck and thence superficially to other parts. (*b*) Rupture of an air vesicle or bronchiole, due to coughing, permitting air to penetrate via the peribronchial tissue to the roots of the lungs and thence through the mediastinum initially to the neck. (*c*) Ulceration of trachea or larynx perforating into the cervical cellular tissue. The latter can be ruled out in the particular case under consideration, the probable explanation of which is to be found in (*a*).

Reports of Societies

MATERNAL MORTALITY: DISCUSSION ON THE "FINAL REPORT"

At the December meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine a discussion was held on the final report of the Maternal Mortality Committee. The discussion was opened by two members of the committee, Dr. W. H. F. OXLEY and Professor F. J. BROWNE.

Dr. Oxley dealt with the terms of reference of the investigation and the considerations which led to the main conclusions and recommendations of the report. He reminded the meeting that the departmental committee was appointed "to advise upon the application to maternal mortality and morbidity of the medical and surgical knowledge at present available, and to inquire into the needs and direction of further research." He described the method adopted for acquiring data. Case reports relating to nearly 6,000 maternal deaths had been analysed by Mr. G. F. Gibberd and Mr. Arnold Walker, and the first object of the committee had been to group together those cases in which a "primary avoidable factor" had appeared to them to have contributed to the fatality. It was found that in 48.8 per cent. of the cases one or more of the following "avoidable" factors was disclosed: (1) an error of judgement in the management of the case; (2) omission or inadequacy of ante-natal treatment; (3) lack of reasonable facilities for treatment; (4) negligence of the patient or her friends. In Dr. Oxley's view it was probable that had the information available to the committee been more complete the proportion of cases showing a "primary avoidable factor" would have been much higher. By a further analysis of the case reports, in each of these four categories an attempt had been made to determine why the defects had occurred, and how they could be eliminated by administrative activity. The recommendations thus evolved formed the basis of the scheme for the definite co-ordinated maternity service advised in the interim report of the committee. Since the issue of this report, however, financial stringency had made any sweeping changes impracticable, and in their stead modified plans for improving the existing machinery were advocated in the final report. The cases in which no departure from established practice was recognized, amounting to just over half of the total, remained to

be considered. In this category are included most of the cases in which sepsis was the cause of death, some of the cases of eclampsia, and the majority of the cases of shock, ante-partum haemorrhage, and of pulmonary embolism. The committee had exhaustively investigated the extent of research work in these matters, and had drawn up a scheme for the direction and encouragement of further research in the various fields involved. Considerable effort had been expended in the consideration of the state of affairs in those countries in which the published maternal mortality figures compared favourably with those of Great Britain. Dr. Oxley was of opinion that the routine service for midwifery in Holland and Scandinavia was superior to ours. In conclusion, he pointed out that what the committee had done in four arduous years was to define the nature and the extent of the defects which were generally admitted, and to advise practicable measures for their eradication.

Professor F. J. BROWNE confined his remarks to one or two matters which had not been dealt with by Dr. Oxley. He defended the recommendation of the committee that the period of clinical training in midwifery for the medical student be extended from three months to six. It had already been adopted by the General Medical Council. He dismissed as impracticable an alternative suggestion which had been put forward by a critic of the report that the extra training should be secured by a period of three months' post-graduate internship. He laid stress on the conclusions of the committee that the future medical practitioner must be educated to regard any operative intervention, except the application of easy low forceps, as unjustifiably dangerous except in a specially equipped hospital. He drew the attention of the meeting to the committee's recommendations regarding the encouragement of specialization in obstetrics. There were whole counties, he maintained, without an obstetric specialist. In many large general hospitals gynaecology, and consequently the most urgent complications of childbirth, were treated by general surgeons. The committee had put forward a strong plea that gynaecological departments staffed by trained obstetricians should be established in all hospitals where they did not already exist. Professor Browne also described the special investigations of the committee into the available evidence with regard to the causation and elimination of sepsis.

Professor GILBERT STRACHAN paid a tribute to the hard work which the committee had expended on their inquiry, but he considered that in several respects the report should be criticized. He felt strongly that there was too much disparagement of British medical practitioners and too much ill-judged admiration of the maternal mortality statistics of other countries. He pointed out, in the first place, that the total number of maternal deaths considered (5,805) represented in round figures the number of women who died in association with 1,450,000 births—roughly the number of births occurring in England and Wales in two years. The committee had arbitrarily laid down eight criteria in the consideration of these maternal deaths, and any departure from the conditions of any one of these criteria had been regarded as a "primary avoidable factor." The sum total of these criteria represented practically a perfect system of ante-natal and intra-natal supervision, and it was hardly surprising that investigation showed the presence of a "primary avoidable factor" in nearly half of these. For the committee to sit in judgement, and to class certain cases as preventable and others as the reverse, savoured a little of being wise after the event. In the experience of most gynaecologists, it was often extremely difficult to decide whether a maternal death could have been prevented or not. Everyone was agreed that public opinion must be educated with regard to the need for ante-natal care, but Professor Strachan considered that the type of propaganda which had been adopted would have the effect of over-emphasizing the dangers of child-bearing in the minds of women. Scare headlines in the public press were not calculated to induce in the pregnant reader that sense of confidence which the report had rightly stressed as being so desirable. An equally grave error was the tendency to produce lack of faith in her personal medical attendant, or in the profession at large. It was also unfortunate that the committee had done nothing towards attempting to educate the public to be ready to make more adequate remuneration for the responsible services involved. In connexion with the recommended staffing of maternity hospitals, the committee had made the serious mistake of comparing the staffing of the Rotunda Hospital, with its resident master, with the staffing of the two London hospitals possessing obstetrical units. They were entirely dissimilar. With regard to the remedies proposed for the admittedly imperfect education of the medical student, he considered that the committee had failed to approach the subject with a full realization of the practical difficulties which confronted the teacher in a crowded medical school where the supply of cases was inadequate. It should have been pointed out that training in obstetrics had, in fact, improved very considerably since the war by the spontaneous efforts of the teachers concerned. One of the main recommendations of the report was that a national maternity service should be established. That a closer linking up of all the services available was desirable was admitted by all, but he asked, What would be the nature of the "supervising authority" which would be set up? Should it be of a bureaucratic nature, with an insatiable desire for form-filling and inspections, the result on obstetrical practice was very likely to be disastrous. The section of the report dealing with "shock" consisted only of a few lines, and was entirely out of proportion to the importance of this aspect of obstetrics.

Dr. T. J. HOLLINS said that he was glad that there had been some adverse criticism of the report. In his opinion the standard of efficiency of general practitioners in Great Britain compared very favourably with that of the practitioners in any country in the world. He related his personal experience in London, where he had failed to gain admission, as a qualified practitioner, to the ante-natal clinic of a teaching hospital. Very little improvement could be expected in the midwifery service of the country unless facilities were open to practitioners for post-graduate study in obstetrics. Mr. W. McK. H. MCCULLAGH considered the report invaluable in showing what remained to be done in the teaching and the practice of obstetrics. As a direct result of the report it had been decided that in the future each medical student at the City of London Maternity Hospital should be guaranteed at least twenty personal deliveries during residence for one month. He wished the committee had further extended its researches so as to consider the cause of death in the 37,000 annual stillbirths. Mrs. IVENS-KNOWLES commended the report because it drew attention to the necessity for a surgically clean technique in midwifery. She thought that an investigation should be undertaken as to the prevalence of morbidity, the effects of which invalided so many women. She considered that obstetrical teaching had improved greatly in the past twelve years, and that the younger practitioners were sending cases into hospital much earlier than hitherto. Dame LOUISE MCILROY, Dr. LETITIA FAIRFIELD, Dr. LEONARD COLEBROOK, Dr. KELSON FORD, and Dr. J. P. HEDLEY contributed also to the discussion.

Dr. OXLEY, in reply, said that there had been no discrimination in the selection of the cases reported. Medical officers of health had been asked to obtain reports of all deaths which would be classed by the Registrar-General as due to, or associated with, childbirth, and they believed that they had obtained a fair sample of such deaths occurring throughout England and Wales. The committee was fully alive to the dangers of terrifying propaganda, and had stressed that point in the report. The statement that in Holland anaesthetics were rarely given in uncomplicated cases was intended to be merely a statement of fact. A serious aspect of the problem seemed to have been missed by those who advocated a more general use of anaesthetics in normal cases. The committee was convinced that the best interests of the mothers would be served by an increasing employment of midwives in normal labour, and would regret such a general demand for anaesthesia as would interfere with the attainment of this end. It was to be hoped that

further research would bring to light a method of relieving pain which could be safely used by midwives.

Professor STRACHAN, in conclusion, remarked that nothing which had been said in the course of the discussion had modified his expressed opinion that the report reflected unwarrantably on British obstetrics, as was shown by the fact that British mortality figures, under admittedly imperfect conditions, were approximately the same as those under the more elaborate systems of Denmark and Sweden.

EDUCATION AND CHILD GUIDANCE

At the twenty-first annual conference of Educational Associations, held at University College last week, Dr. WILLIAM MOODIE delivered, on January 3rd, a lecture under the auspices of the Child Guidance Council on educational problems in a child guidance clinic.

Dr. Moodie said that the number of children referred for backwardness was only about 20 per cent., but that 65 per cent. of all cases showed some relative backwardness, some discrepancy between their potential and their actual performance. The child with about 85 per cent. intelligence was a difficult problem, for he came between the normal and the defective. Difficulty arose when too much was expected of the child by either himself or his parents; if properly handled such a child might remain perfectly pleased with himself. Many children were backward in special subjects—for instance, could not read, write, or do sums at 11 years. Children who could not read suffered, not from a word-blindness, but from a blindness to shape and position. Some intelligent children developed this power of appreciating the symbol late, but were afterwards normal. Specific defect in calculation, which required abstract thought, was nearly always due to emotional disturbances around adolescence, or to some special emotional reason why calculation itself should be selected—an antipathy, for instance, to a particular teacher. Children with supernormal intelligence were often badly handicapped through being held back from work by the doctor on the pretext that they must rest their brains. It would be just as sensible to deprive them of food because they were growing too fast. No amount of cleverness would make up for the lack of social education in the school group. Such children were often wrongly accused of being lazy, when what they needed was fundamental instruction. Special sense defects, such as partial blindness or deafness, were the cause of many difficulties. A partially blind child might not be able to read the blackboard, but often—especially if the trouble was congenital—could go on for a long time without being detected. Partial deafness was much more subtle, because it fluctuated considerably and often was not present at the medical examination. Children could mask it extremely well. Tone-deafness—that is, selective deafness to certain wave-lengths of sound—might prevent a child from understanding speech, though he might be able to lip-read. Tinnitus, resulting from suppuration or degeneration within the ear, might often produce apparently insane violence. Fatigue was the cause of many nervous disorders, and might be due to chronic interference with sleep in cramped or disturbed quarters. Acetone in the breath was a conspicuous signal of fatigue. Dr. Moodie thought that the importance of sepsis was overrated. In conclusion, he said that he doubted whether society was not wrong in the handling of its young. On the one side medical psychologists ascribed the manifold mental troubles of the present day to repression during childhood; other persons condemned punishment, and police courts gave wholesale probation. Many of the so-called problems of the clinic would never even have been produced as problems if the children had been handled differently in their earlier days. The swing away from guidance, advice, and discipline was wrong. Wholesale probation was unconstructive and harmful. Co-operation between child guidance experts and educationists should make clear the difference between repression and discipline, freedom and licence. Enough knowledge existed on which to go forward with confidence, and to adopt a little more hard handling of children.

The Competitive Spirit in Games

Dr. G. E. FRIEND took the chair at a meeting of the Medical Officers of Schools Association on January 6th, when Dr. R. COVE-SMITH spoke on the risks of competitive games and sports. He said that men and women as a whole were neglectful of the body, until it protested by discomfort or by disease, which might have been prevented by a little anticipatory thought. The tripartite nature of the human body must be remembered: man should be trained, like a dancer, to keep step with the rhythms of life. Games should have a mental and moral value as well as a physical one; they should be a creative outlet. In practice, however, physical training was too often in the hands of people whose ideal was a "Sandow." He classed sportsmen into three groups: those who played themselves, those who watched others playing, and those who could not get their excitement merely from watching but had to bet. The substitution of more spontaneous forms of play was not only desirable but essential; camping and scoutcraft were better than games and morris dancing; fencing and swimming, than the organized games of the schools. The results of the competitive spirit were that an emotional was added to a physical strain; that the specialist was overtrained and the bad player neglected; and that a wrong kind of training was given to the future citizen, whose motto should be co-operation, and not competition. Dr. J. LAMBERT said that the modern tendency of physical training was to introduce the competitive element, which formed a welcome break in the monotony of drill. He doubted whether any game had ever been non-competitive. Competition was a natural instinct. Serious injuries were rare in children under 9, whose bones and muscles were elastic, and who would not run themselves out in the way the older child did. In two preparatory schools where he was medical officer, each containing about sixty boys, he had encountered twenty-four epiphyseal and joint injuries, three fractures, thirty-one abrasions, cuts, and bruises, and thirteen muscle and tendon injuries. In this school Rugby, cricket, and hockey were played. In another school, where soccer was substituted for Rugby, he had met fourteen epiphyseal and joint injuries, fifteen abrasions, cuts, and bruises, five muscle and tendon injuries, one fracture, and one concussion. In all his thirty years' experience he had only seen two severe fractures. In ten years as medical officer to a great public school he had seen 152 joint and dislocation injuries, twelve fractures, ninety wounds, cuts, and bruises, eighty-eight concussions, thirty-six muscle injuries, eight eye injuries, seven dental injuries, and five visceral injuries. The worst fractures occurred in cricket, and were the result of inattention in the field. There was always a danger that an enthusiastic captain or master would set up a tyranny, and the school doctor could exercise wise diplomacy in this respect. It was very difficult to harm the heart of the schoolboy if it had not already been damaged by a toxin. The convalescent from any illness should be medically examined. Runs in most schools to-day were short and not dangerous. The CHAIRMAN agreed that the team spirit counted for a great deal in the useful citizen, but that competition needed careful watching. Mr. H. G. SWEENY said that the only evil was excess, and the golden mean was for every individual to find his own limit, so that both competition and co-operation played a part. Mr. R. E. ROPER pointed out the fivefold strain placed on children in the summer term—certificates, prizes, school examinations, school sports, and swimming sports—and urged that sports should be held at the beginning of the autumn term. Miss C. S. BANKS said that girls' schools were much better off in respect of their physical training instructors than boys' schools. She had noticed that doctor parents were terribly afraid of letting their children take the normal course of drill and sports.

Dr. COVE-SMITH, in reply, said that because we were steeped in the system of competition it did not necessarily mean that we ought to go the whole hog with it. It was

the team spirit he liked to see, not the competitive factor. He had no doubt that girls' schools were much better off than boys. He agreed that strain only occurred when the contestant was unfit, and that watch should be kept on those who had colds, influenza, or tonsillitis. Young children liked to build up fantasies around their play, and should not be too much supervised. It was most important to get better physical training instructors and to space out the programmes of sports.

MEDICO-LEGAL DIFFICULTIES

At the last meeting of the Paddington Medical Society Dr. JAMES NEAL, secretary of the Medical Defence Union, delivered an address on some of the medico-legal difficulties confronting medical practitioners.

Dr. Neal reviewed the various circumstances and conditions in which a practitioner might be called upon to justify his professional actions. Allegations of negligence, particularly by aggrieved, hysterical, or insane patients, were always a possibility. The treatment itself might be criticized, and omissions alleged. All that was necessary was that a patient should conceive the idea that he might have made a more rapid recovery for him to bring an action on account of loss of wages, loss of health, expenses to the seaside, and so on. Such actions often involved a counter-claim in respect of fees charged. Even when the action failed the doctor might have to pay his own costs, since many such litigants were "men of straw." There was no hard-and-fast rule regarding the instructions which a doctor should have given a patient or his nurse about treatment prescribed: his responsibility would depend on the facts of a case, which were for a jury to determine. The judicial bench might be tolerant; juries were not always so. No reply to an allegation of negligence should be made except on advice. A doctor's position might be gravely prejudiced by unwise letters. In the routine work of practice a medical man should not only be careful, he should avoid any appearance of carelessness. Outward signs of care were always worth while. If work had been done with obvious conscientiousness even a stupid error of diagnosis was not likely to cause disaster. In regard to a doctor's responsibility for the carrying out of prescribed treatment it was a question whether a surgeon could be held fully responsible for the duties of a trained nurse when complete supervision was impossible. Lately there had been a tendency to limit responsibility to duties carried out under direct supervision of the surgeon. The question of the responsibility of surgeons and anaesthetists might arise any day. It was indiscreet for an anaesthetist to operate, except in confinements. In regard to abortion, Dr. Neal pointed out that the present law, however leniently it might on occasion be interpreted, was that any operation with such an object, except on account of definite pathological conditions, was illegal, and amounted to manslaughter. A contract to provide treatment should be definite. An account should be rendered to the person liable for payment. A parent was liable for the treatment of a minor; a husband, for the treatment of his wife. Employers were not liable, except by agreement, for the treatment of their employees. No examination of an employee or domestic servant should be carried out except with the full permission of the examinee. No information concerning a patient's condition should be divulged to a third party without the patient's consent. Information to the police required careful consideration. Information regarding attempted suicide should be given only in special circumstances. In cases of suspected criminal abortion, where no objective sign existed, it was wise to proceed as in cases of natural abortion. Even when the physician was satisfied that there was criminal interference, it was not necessary to give information, providing the patient seemed likely to recover. If, on the other hand, the patient died, it was incumbent on the physician to report the case and to give full information to the coroner. If it was probable that the patient would die, the doctor should urge her to make confession to the proper authorities.

Reviews

AN INAUGURAL LECTURE AT CAMBRIDGE

In his inaugural lecture last November Professor W. LANGDON BROWN gave an account of *English Medicine and the Cambridge School*,[1] which delights the reader both by the charm of its style and the wealth of interesting information thus pleasantly presented. In the fifty-two pages of the beautiful type of the Cambridge University Press the regius professor of physic paints a clear picture of events during four hundred years, in which the dark background of the first three centuries shows up with Rembrandtesque effect the bright era of the physiological school at Cambridge since the advent of Michael Foster in 1870. As a former pupil he draws a fine portrait of W. H. Gaskell, whose discoveries were "extended and completed" by "the splendid accuracy of Langley's mental microscope." Of the achievements of the great biochemical school he speaks as one of its first nurses, for after Sheridan Lea's health broke down in 1894, he, and later Dr. H. Eichholz, kept physiological chemistry going until the splendid services of Sir F. Gowland Hopkins were obtained. Taking a broad view of what medicine should be, he points out the increasing tendency to approach it from a psychological aspect, and later pleads that in Cambridge the students' scientific studies should be given a humanistic trend. History repeats itself. In 1570 the Elizabethan statutes relaxed the obligation of medical students to take an Arts degree, with an evil influence on their general education. Since the war there has been a tendency in the same direction, and there is now an earnest effort to obviate such a falling from grace; this the regius professor feels will duly succeed, for Cambridge has "always been adept at putting new wine into old bottles." The inaugural lecture ends with a light and happy touch; for, recalling the "almost excessive joy" with which one of his predecessors, John Gostlin of Caius, returned to Cambridge in 1619, Professor Langdon Brown registers the pious hope that "the higher levels" of his nervous system will inhibit "any unseemly manifestations" of his own feelings.

THE AIMS OF MEDICINE

Sir GEORGE NEWMAN has just issued, under the title *The Rise of Preventive Medicine*,[2] what may perhaps be regarded as his most ambitious or most comprehensive volume. It consists of the Heath Clark Lectures, 1931, which he delivered at the London School of Hygiene and Tropical Medicine, and makes an excellent book both in content and in format. The style is, not unexpectedly, often touched with a rhetoric which suits the delivered lecture better than the printed page; but the chapters follow one another with a logical precision, and constitute an admirable survey of historical progress in the way of health. The contributions of folk-lore and magic, of Egyptian civilization and the Mosaic law, of the Greek spirit and the Arab conquests, of the manor, the Church, and the guilds in the Middle Ages, of the Renaissance with its anatomical and physiological research, of later clinical studies of communal disease, of pathological and bacteriological discoveries, and of collective health organization, are all in turn effectively outlined, and there is throughout the book the sustained interest of a continuous theme.

[1] *English Medicine and the Cambridge School: An Inaugural Lecture.* By W. Langdon Brown, M.A., M.D., F.R.C.P. London: Cambridge University Press. 1932. (Pp. 52. 2s.)

[2] *The Rise of Preventive Medicine.* By Sir George Newman, K.C.B., M.D., F.R.C.P., Hon. D.C.L., LL.D. Heath Clark Lectures, 1931. London: H. Milford, Oxford University Press. 1932. (Pp. 270; illustrated. 10s. 6d. net.)

This theme is, in the author's words, that "the ideal of medicine is the prevention of disease, and the necessity for curative treatment is a tacit admission of its failure; yet the ways and means of prevention from the earliest times have constituted a part of the history of human conduct in the individual and the community rather than being merely instruments of the medical art." Thus Sir George Newman ranges himself with those who regard the medical profession primarily as a body of social workers co-operating with a large number of others in promoting social welfare, rather than as technical investigators in the laboratory of the schools or of the human body. There is a cleavage of attitude between these views which is important, but a community of purpose serves to harmonize them. The author's presentation of his subject serves well to show this, both in his treatment of the applications of discoveries and by his illustrations drawn from the life and work of a number of notable members of the profession.

At the outset Sir George Newman sets forth the threefold aim of medicine. This, abbreviating his words somewhat, is: "First, the provision of a remedy or cure for disease (curative medicine); secondly, the avoidance or prevention of its causes and, when it be established, the prevention or modification of its results (preventive medicine); and, lastly, the practice of a way of life which preserves the natural defences of the individual or the community (conservative or constructive medicine)." The author recognizes, of course, that these are three aspects, rather than three divisions, of medicine—a threefold aim, and not three separate or separable aims—but, even so, we think a slight modification of his analysis would be preferable. As it is of some importance to establish a uniformity of idea and statement, if not also of nomenclature, in this matter, we suggest that the third of Sir George Newman's aspects, as he sets them out, is really included in his second (especially as he uses the word "avoidance" as well as "prevention"). There would be a clearer and more advantageous differentiation if the second aspect were held to include the avoidance or prevention of disease-producing factors by the maintenance of both a favourable external environment and a healthy physiological balance which constitutes the internal environment (preventive medicine), and if the third aspect were held to be the raising of normal bodily or mental functions and activities—of the whole personality, in fact—to the highest power of which they are capable (constructive or perfective medicine). Stated more briefly, we should then have as the threefold aim of medicine the remedying of departures from the normal, the avoidance of departures from the normal, the enhancement of the powers of the normal. The first has been the traditional purpose, the second is now a fully realized objective, and the third is being increasingly envisaged.

In his exposition of a vast subject Sir George Newman has probably over-emphasized some of the contrasts of experience and of method between the various stages into which he had divided the story of the progress of medicine in its preventive aspects. He may be held, as he himself suspects, to have introduced some matters which are rather remote from, or somewhat irrelevant to, the immediate subject. It may be said, too, that in his later chapters he has disregarded, or insufficiently expressed, the influence of the organized medical profession on public health and preventive movements. He does, indeed, indicate some of the ways in which the Royal College of Physicians exercised its powers or used its opportunities. But, during the century of its existence, the British Medical Association has been very definitely instrumental in bringing about medical reform and improvement in Poor Law administration, in promoting public health measures, and in the establishment of the school medical service, and in converting the national health insurance scheme into an effective service; and this might well have received some mention or acknowledgement. The medical profession and the public should, however, be grateful to Sir George Newman for his comprehensive, ordered, and illuminating review of the subject of which he has for long been a brilliant exponent.

ELECTRO-SURGERY

The history of surgery in the last few decades has consisted in the main in the application of our increasing knowledge of physiology, bacteriology, and pathology to those problems of disease in which methods of extirpation offered the only way of arrest or eradication. These sciences having reached a temporary plateau in the curve of their development, the surgeon, ever in search of new principles and methods, has had recourse to the new physics. The extraordinary properties of radium and *x* rays offered such new principles and methods, and the results have inspired great hope for the future treatment of malignant disease. But methods of extirpation of disease processes have still to be used extensively, and the application of our improved understanding of the physiological effects of high-frequency currents has become a feature of modern surgery. Research in this relatively new branch requires close co-operation between the electrical expert, the pathologist, and the surgeon.

The ultimate object of electro-surgery is stated shortly by the authors of the most recent book on this subject[3] to be the generation of heat in diseased tissues by the passage of a high-frequency electrical current through that portion of the body. The distinction from electro-cauterization is clear, for this involves the direct application of high temperatures to the passive part to be operated on, while in electro-surgery the tissue is an essential part of the circuit, the intensity of heat produced depending on the current density generated at that part. It is the concentration of the high-frequency current into small areas which constitutes the main electrical problem in this method. The authors of the present volume have introduced a chapter on the physics of high-frequency currents, which will serve as a reminder of the underlying principles for those who have previously studied the matter, but as an introduction to the subject it is rather disappointing. The relative merits of spark-gap generators and vacuum-tube generators are, however, put forward clearly and succinctly. The histological changes produced in normal tissues by high-frequency currents are well dealt with under the heads of electro-desiccation, electro-coagulation, and acusection, with indications for these different methods of operation. Technique and equipment are described, the fruits of long experience and care being everywhere evident. The description of precautions against the spilling of malignant cells and details of post-operative care—particularly in cases where large cavities are created—will be of great assistance to surgeons using this method. The senior author (Dr. Kelly), who was one of the pioneers of electro-surgery, indulges here and there in forecasts of future development in a pleasant and stimulatingly prophetic manner. Discussion of the use of electro-surgery in the principal areas of surgical intervention, with details of particular operations, is presented with caution. The method has its dangers, and the authors are at pains not to minimize them. It is in skin tumours that the most striking results are shown. The dangers and difficulties are obvious when so powerfully destructive an

[3] *Electrosurgery*. By H. A. Kelly, M.D., LL.D., F.A.C.S., and G. E. Ward, M.D., F.A.C.S. Philadelphia and London: W. B. Saunders Company. (Pp. xxii + 305; 382 figures. 35s.)

agent is used in regions close to large vessels, as, for example, in thyroidectomy, tonsillectomy, etc. The sections dealing with urological problems abound with important information on technique, instruments, and indications. Cystoscopic photographs, with instruments in position and actually at work, are an important feature of this part of the book.

The authors have succeeded in presenting just enough of the various applications of this method to interest and stimulate surgeons.

ADVANCES IN CYTOLOGY

During recent years the John Innes Horticultural Institute at Merton has become one of the most active schools of plant genetics in the world, and when Newton joined the staff he became the nucleus of a group of brilliant young cytologists. Newton died, and his mantle passed to Darlington. A steady stream of cytological papers, many of them highly controversial, whetted the appetites of all of those to whom cytology is important. A very hearty welcome, therefore, awaited Dr. DARLINGTON'S latest book on *Recent Advances in Cytology*,[4] for in it his contributions to fact and to theory, which simply cannot be neglected, are presented. It is not really a textbook on cytology, for it deals only with the nucleus and refers to extra-nuclear constituents of the cell only in so far as they are related to the nucleus. It consists of three parts: the first forms an excellent introduction to cytology for the student; the second is a summary for the research worker who seeks information in classified observation; the third, which possesses a particular importance, is a theoretical treatise in which Dr. Darlington's own views are developed and which is addressed to the general biologist. No one of these will find this book easy to read or the arguments easy to follow. The fault lies not with the presentation so much as with the subject, but, be it easy or difficult, the book cannot be disregarded. It heralds the beginning of a new epoch in cytology in that it marks the transition from a phase that has been concerned purely with description to one which is bound to become more and more concerned with deduction. It is seldom that one meets within the compass of 560 pages so much fact and so much attractive theory. Particularly fascinating is the chapter on the evolution of genetic systems. This may be strongly recommended to any who wish to become aware of the bearing of the facts of cyto-genetics upon evolution theory. There are appendices upon cytological interpretation and recent improvements in cytological technique, a sufficient glossary (which is very necessary), and a fairly full bibliography (in which there are to be found many minor errors).

It should be possible for most biologists to read, understand, and appreciate this book in a few months' intensive study. And it must be read and understood by anyone who, in order to explain biological phenomena, invokes the aid of the gene or of a faulty chromosome behaviour.

PRACTICAL MEAT INSPECTION

The starting-point of the effective regulation of the meat supply of this country is the inspection of carcasses in slaughterhouses by meat inspectors working to plan and following the approved code of judgement laid down for England and Wales by the Ministry of Health. For the guidance of meat inspectors in carrying out their duties under the code a useful manual has been written by the senior sanitary inspector of Whitstable,[5] who describes himself as a "practical inspector," and without aspiring to "ultra-scientific detail" treats his subject from a practical point of view. Among the topics dealt with are physiology and comparative anatomy, slaughter and the dressing of carcasses, and the malformations, abnormalities, and evidences of bacterial and parasitic infection which may be found in meat animals. The code is quoted and its application in the case of the various lesions explained. The problem presented by trichinosis is discussed. The view is expressed that the Temple gun, Mark V, is the best mechanically operated stunning instrument available at the present time. The author's disclaimer above notwithstanding, his terminology is in general most orthodox. *Acarus*, however, is not an insect, and *Linguatula*, despite its worm-like appearance, belongs to the class *Arachnida*. The closing chapter of the book contains an excellent account of refrigerating plant, and of refrigeration as used for home-killed and imported meat. This section includes an informative reference to the occurrence of *Onchocerca gibsoni* in Australian beef.

The author, from his long experience, writes with conviction, and we feel sure that his work will be appreciated by meat inspectors. We think, further, that it should prove of service and interest to candidates for the Diploma in Public Health, of whom a practical acquaintance with the site and appearance of the lesions produced by enzootic disease, as well as a knowledge of the differential points in the comparative anatomy of the meat animals, is nowadays expected by examiners.

Notes on Books

A small book, in which Dr. ZUND-BURGUET has collected descriptions of the various theories of *Sound Conduction and Hearing*,[6] has been translated by Mr. Macleod Yearsley. Its chief objective, however, is to overturn the resonance theory of Helmholtz. The author supports a view in which the chain of ossicles is held to act as a mechanism of accommodation. He has taken much trouble to search for records of old writings on the subject, and has produced a compilation which may be useful to physiologists. He also gives a good account of the theory which he considers has supplanted the resonance theory of Helmholtz. It appears that the correct view of this matter was put forward by Hippocrates.

From time to time there arise faint protests from that patient carrier of burdens, the medical student, against the cruel overloading of the medical curriculum at the behest of specialists in various branches of medical science. Licensing bodies struggle feebly against the importunities of these enthusiasts, but steadily syllabus after syllabus and examination paper after paper are laid upon the helpless undergraduate, who carries them for longer and longer, so that his average sentence is now nearly seven years. Small wonder, then, that there is a growing dissatisfaction with the curriculum, and that teacher and taught alike are talking of the need for drastic reform. In Professor RASMUSSEN'S monograph *The Principal Nervous Pathways*[7] we have an example of what in one American medical school the student is expected to learn and digest in the way of detailed information. The book comprises a series of twenty-eight diagrams, charts, and verbal schemes representing all the known masses of gray matter and fibre tracts in the central nervous system.

[4] *Recent Advances in Cytology*. By C. D. Darlington, D.Sc., Ph.D. Foreword by J. B. S. Haldane, M.A., F.R.S. London: J. and A. Churchill. 1932. (Pp. 577; 109 figures; 8 plates; 66 tables. 18s.)

[5] *Practical Food Inspection. By Charles R. A. Martin. Vol. I: Meat Inspection.* London: H. K. Lewis and Co. 1932. (Pp. 312; 138 figures. 15s. net.)

[6] *Sound Conduction and Hearing.* By A. Zund-Burguet. An Historical, Critical and Experimental Study. Translated by Macleod Yearsley, F.R.C.S. London: John Bale Sons and Danielsson, Ltd. 1932. (Pp. 139. 8s. net.)

[7] *The Principal Nervous Pathways.* By Andrew Theodore Rasmussen, Ph.D. New York: The Macmillan Company; London: Macmillan and Co., Ltd. 1932. (Pp. 73; 28 figures. 12s. 6d. net.)

The diagrams are thickly sown with names, and are all highly complex. The author's stated object has been to present to the student "those facts which will be used most directly in the immediate future." When we say that one of the diagrams represents the rhinencephalon and has over fifty names in it the unpractical character of the monograph will be apparent. It contains no selection of what is clinically valuable, and is quite unsuitable for the medical student. For the neurologist the charts and diagrams may have some interest as a work of reference, though for this purpose the text is too elementary.

The eighth edition of *Lippincott's Quick Reference Book for Medicine and Surgery*[1] has been enlarged by the addition of new matter in order to bring it up to date. The previous edition appeared in 1930, and opportunity was then taken by Dr. REHBERGER to effect a complete revision of the whole of the material; there is therefore little change of consequence to record, and the *Quick Reference Book* can still be commended as a monument of industrious compilation. Originally prepared to meet the practical needs of the author, who was then in isolated practice in the mountains of British Columbia, its aim is to give a digest of present knowledge in respect of general medicine, surgery, and the specialties. The ten parts into which this immense volume is divided are headed as follows: general medicine and surgery, including nervous and children's diseases; gynaecology; genito-urinary diseases; obstetrics; skin diseases; eye diseases; ear diseases; nose diseases; throat diseases; and orthopaedics. Illustrations are abundantly supplied throughout the text, and there are coloured plates, many borrowed from *Larousse Médical* and printed in France. An alphabetical list of drugs is supplied, with their dosage, solubility, method of administration, physiological and toxic actions, and uses.

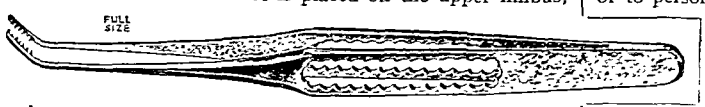
[1] *Lippincott's Quick Reference Book for Medicine and Surgery.* By George E. Rehberger, A.B., M.D. Eighth edition, revised. London: J. B. Lippincott Company. 1932. (Illustrated. 65s. net.)

The Alexander Pedler Lecture, given before the British Science Guild in November last by Sir Frederick Hobday, principal and dean of the Royal Veterinary College, has now been published as a pamphlet (6, John Street, Adelphi, W.C.2, 1s.) The title of the lecture was "Animals as a national asset and responsibility." Speaking of the recognition by foreign countries of the value of intensive research into the problems of animal diseases and their relation to public health, Professor Hobday said: "Great Britain has been very much behindhand in this respect, although during the past few years, by the establishment of an Animal Research Institute connected with the Royal Veterinary College, Camden Town, London, and an Institute for Animal Pathology at Cambridge—also by the introduction of university veterinary degrees and a post-graduate diploma in veterinary State medicine—there is a good prospect that well before another decade has passed the value of veterinary research will be recognized in Great Britain as being of as essential value to the public health of the nation as it is in other countries of the world."

Preparations and Appliances

UPPER FIXATION FORCEPS

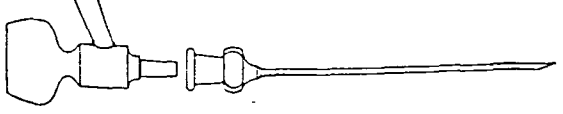
Mr. D. PRIESTLEY SMITH (Birmingham) writes: The forceps shown in the accompanying figure are for fixing the eye in cataract extraction. One foot is placed on the upper limbus,



and the other 5 or 6 mm. higher up on the globe. They are then closed. This gathers up the intervening conjunctiva to the limbus, where it forms a fold or pleat held at its base in the forceps. This affords very good fixation. The corneo-scleral section is now made forthwith, the knife cutting out immediately behind the feet of the forceps—that is, through the posterior layer of the conjunctival fold. This procedure makes a good conjunctival flap. The forceps are made by Down Bros., Ltd., St. Thomas's Street, London.

A SIMPLE ARTIFICIAL PNEUMOTHORAX NEEDLE

Dr. J. WOOD WILSON (Outwood, near Wakefield) writes: For some time I have been endeavouring to find an artificial pneumothorax needle for refills simpler than, and yet as efficient as, those now commonly employed. The following is a description of the needle I am using at present.



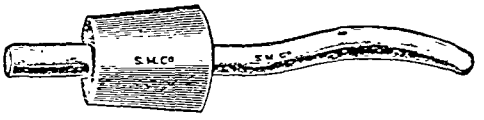
The essential feature, as can be seen from the illustration, is the short metal piece with a record-fitting nozzle to take a needle, a side branch for the attachment of the completed needle to the artificial pneumothorax apparatus, and a flat surface to fit into the hand. The actual needle used by me is an ordinary serum needle, size 12-10, with record mount. This is fitted to the nozzle with a half-turn, and the needle is complete. The advantages of this type of needle are many. It is cheap, as only the serum needles require replacing, and an adequate supply of sharp needles can be available at little cost. It is convenient and expeditious when a number of refills have to be given in one session, as only the serum needle is changed for each patient, and there is not the usual trouble of fitting the rubber connexion to the needle. The bore of the needle can be altered at will, and any desired bore used according to the needs of the patient, or to personal preference. Similarly, the length of the needle may be altered to suit the individual case. The obvious disadvantage—lack of facility for clearing a blocked needle—occurs infrequently in my experience.

The metal fitting was made to my order by Messrs. Vicarey, Davidson and Co., surgical instrument and dressings makers, 172, Bath Street, Glasgow, C.2, and has given me every satisfaction.

ANAESTHETIC DROPPER

Dr. RICHARD A. MANCLARK (St. John's Hospital, Lewisham) sends the following description of an anaesthetic dropper which he has had made and used with success in the administration of chloroform, ether, and mixtures of chloroform and ether.

The chief advantage of this dropper is that it can be used for a perhalational method by the very simple way of holding the anaesthetic bottle first horizontally and then gradually more vertically; the rate of dropping and the size of the drops can thus be varied to suit the wishes of the anaesthetist—the more vertically the bottle is held the larger will be the size of the drops and more rapid the flow. Where insufficient anaesthetic is obtained by the above method, the dropper may be used as a douche by raising the bottle up



and down vertically, and as much anaesthetic can then be obtained as required. Should, however, the anaesthetic spurt out from the small hole in the dropper, this indicates that the douching is being done too jerkily. As regards cleaning, the simplicity of its construction makes that an easy matter with a pipe cleaner or fine wire.

The dropper is composed of a metal tube, as shown in the accompanying diagram. It is made for me by the Surgical Manufacturing Company, Mortimer Street, W.1, and sold at a moderate price.

British Medical Journal

SATURDAY, JANUARY 14th, 1933

MEDICAL EDUCATION

Very opportunely comes the final report of the Commission on Medical Education, organized by the Association of American Medical Colleges, and helped by several of the medical schools of Canada and by the Rockefeller and Carnegie Foundations.[1] The only Canadian member of the Commission was Sir Robert Falconer, president of the University of Toronto, the remainder being eminent representatives of a number of universities in the United States, not all of them members of the medical profession. The report appears in the form of a large, well-printed volume of some four hundred pages, exclusive of an appendix containing a considerable number of tables. It is perhaps a little wordy, especially in its earlier chapters ; but it contains such a full, effective, well-considered review of the whole subject of medical education that it should be most helpful to all who in this country are giving their minds to the matter with which it deals: indeed, it would scarcely be an exaggeration to describe the volume as almost indispensable for such persons. The report has reference, of course, primarily to the conditions in the United States of America, and to a lesser extent to those of Canada, but the problems presented are much the same as in this country, and there is a long chapter, entitled " Medical education in Europe," which describes with surprising accuracy the position in Great Britain, and, as far as we can judge, with equal correctness that in Germany, France, Austria, Switzerland, Holland, Denmark, and Sweden.

The order of consideration is unusual, but no less logical than its opposite, which is the ordinary method of approach. Medicine is viewed throughout mainly as a section of social welfare, and medical education as part of the national health programme. The public aspects of medicine, therefore, and the needs of medicine in order that it may properly perform its national functions, are first considered and the supply and distribution of medical practitioners described. Next is taken the question of post-graduate study and the training of specialists. This is followed by a valuable chapter on " the internship " and the way in which this can be made most useful prior to a full licence to practice ; and by one on " medical licensure," which is none the less interesting because it has reference to the various " cults " that trouble America more than they do Europe, and to what is called " substandard " training and licensure. " Compromise," the commissioners declare, " with substandard training for those who deal with the health of the people is not a sound public policy." Then follows the main and detailed consideration of the medical course and curriculum, and only then, last in order, is pre-medical education discussed.

In general, the British and American systems of medical training approximate to one another and differ materially, in some respects fundamentally, from those of the continental European countries. Conditions in the United States have all along presented peculiar difficulties, but of late years there have been great improvements. It is satisfactory on reading the report on medical education in Great Britain to gather the impression that it is, on the whole, the best in the world, and now shows fewer imperfections than that elsewhere. But national requirements and the range of knowledge have both so extended as to make revision imperative, and it may be that there are even certain Continental methods which, with suitable modifications, it would not be unwise to adopt. In the Commission's invaluable chapter on " the medical course " the changes in requirements and in medical practice are set out, the main purposes of medical training are formulated, and some of the defects of that training, both general and in regard to particular subjects, are described. It is insisted that " topics are presented too frequently from the standpoint of the special interest of the teacher and from the aspect of technical details. There is an overemphasis on laboratory work as a method of instruction. . . . The course should be regarded as a unit, and the instruction in individual departments ought to be presented with respect to the whole." There is also the pregnant sentence that " the medical sciences form not only the foundation but the scaffolding of medical learning, and are built upon the principles of biology, chemistry, and physics." The importance of the personality, understanding, and enthusiasm of the teacher, and of attention to the needs of the individual student, are stressed.

It may be gathered that the Commission would agree, as a general statement, that four of the principal needs in a revision of medical training are: (1) the bringing of clinical methods into close relation with the preliminary sciences and with anatomy and physiology ; (2) the permeating of all teaching with the idea of prevention, and demonstration of its methods ; (3) emphasis on the importance of the psychological aspect of medicine and the treatment of the person rather than of the disease ; (4) recognition of the concept of medicine as a social agency. Suggestions for the detailed improvement of the curriculum are wisely implied rather than categorically stated, and, in this connexion, the necessity for gathering the opinions not merely of teachers, but also of graduands, both recent and older, has been kept in mind. In this central part of the report will be found a wealth of fact and of mature opinion based upon wide experience, together with a true " university " outlook. Even if some will not be able to read the whole volume with care, this part of it, together with the chapter on the internship, should be seriously studied by all who have any responsibility in this matter or who desire to contribute any guidance towards necessary reforms and improvements.

[1] Final Report of the Commission on Medical Education. New York: Office of the Director of Study, 630, West 168th Street.

MEDICINE AND THE MINISTRY OF HEALTH

On another page we review Sir George Newman's comprehensive survey of "the rise of preventive medicine." The profession and the public have come to look to Sir George Newman's office and chair in Whitehall for such illuminating reviews covering a longer or shorter period of time. He has, during his many years' occupancy of that chair, established the expectation that the Chief Medical Officer of the Ministry of Health will always give evidence of a broad outlook, of wide professional contacts and sympathies, and of an understanding of the needs and conditions of medical work, in harmony with those needs and conditions as seen by the practising members of his profession. Happily, there is no reason to assume that Sir George Newman's latest book is his last. We may look forward for several years yet to his annual reports, both on the state of the public health and on the health of the school child, and thereafter we may anticipate the fruits of a fuller leisure. The time of retirement, however, cannot be very far distant, and before it arrives thought will properly be given to the selection and initiation of an appropriate successor. The medical profession cannot be indifferent on a matter such as this, and, indeed, it is true to say that for the past year or two the possibilities of the situation have been much in the mind of many of its members.

There can be no question whatsoever, here and now, of personalities: it is the essential requirements of the post alone that have to be considered. It seems desirable that they should be formulated at least in a preliminary fashion. We believe that if those of greatest influence in the profession, and those who are most fully acquainted with these requirements, were consulted, three things would be unanimously urged. The first is that selection should be made from the widest field in order that the best person may be chosen. Naturally the senior medical officers of the Ministry itself must be considered, but we believe that they would be among the first to agree that consideration should not be confined to them alone. Speaking quite generally and without any reference to the present occupants of those offices, it is plain that qualifications which make a first-class departmental head are not of necessity those required for the highest post. Indeed, it is possible that, however efficient such a departmental officer may be, and however eminent in his own line, the comparative isolation in segregated work over a period of years may itself prove a handicap to success in the wider office. It should be remembered that Sir George Newman himself was appointed from outside the Civil Service. He was a local medical officer of health and a teacher who had kept himself not only in close touch with his colleagues in the public health service, but in constant association with those practising all branches of his profession, not least with the large body of general practitioners. This has been of the utmost value in assuring the success, under whatever difficulties, of the health services of the country. It is contacts and qualities such as these that have to be looked for, as well as great technical knowledge and administrative ability. Hence the widest possible field of choice should be regarded as open.

As a second primary requirement we should urge that the conditions of appointment of the Chief Medical Officer should be such as to ensure the right of direct access to the Minister himself whenever necessary. This, as is well known, obtains at present, and if it had not been so, or if this were altered, there would undoubtedly be extreme dissatisfaction in our profession. Indeed, it would be difficult to overestimate the complications that might arise in certain contingencies. The Medical Department of the Ministry of Health is differently placed from the medical department of some other Government offices. It is, in large measure, the Ministry itself, and represents the body through which almost wholly, directly or indirectly, its knowledge must be acquired and its action taken. The technical and the administrative aspects can here with difficulty be dissociated; but nothing more is claimed than that, should the need appear, the professional voice should have the right of an independent hearing.

The third requirement should be that the offices of Chief Medical Officer to the Ministry of Health and Chief Medical Officer to the Board of Education are not separated. Under the law of to-day the determination of policy in that public health service which is called the school medical service is vested in the Ministry of Health. By an interdepartmental arrangement, nothing more, its administrative supervision is farmed out to the Board of Education. It is only the fact that the Chief Medical Officer to the two Ministries is the same person that has saved the service from elements of discord or disruption. The best solution might be for the Ministry of Health to exercise full control, as provided for by Act of Parliament; but, short of that, the appointment of two chief medical officers would tend to disaster. We can hardly doubt that this and the other two considerations will be kept fully in mind when, at some time in the near future, the situation matures for action.

RISE AND FALL OF THE ROD

There are signs of a reactionary change among those who teach us how to manage our children. A few years ago not a voice could be heard in defence of corporal punishment, and we were taught that children must be allowed to do pretty well as they liked, and only be deflected gently towards some other interest if they persistently chose a dangerous or unsocial occupation. It may be the inevitable reaction from an extreme position, or it may be due to the horrible results visible in other people's children to-day, but the Conference of Educational Authorities meeting at University College last week heard two of the leading experts on child psychology advocate more and better punishment. Dr. F. C. Shrubsall, addressing the Child Study Society, began by saying that the psychiatrist might meet patients whose misfortune could be traced back to punishment,

but those dealing with the delinquent saw plenty of cases in which people were brought almost to the foot of the scaffold for lack of punishment at an earlier stage. He said that both points of view were right, and that a balance must be struck between them; and he would have found the psychiatrist addressing the Child Guidance Council at the same conference in full agreement with him. Dr. William Moodie, of whose lecture we give an account at page 63, spoke strongly in favour of firmer discipline, and asked whether society was not all wrong in its present attitude towards child training. The revolt against what was perhaps over-punishment in the Victorian era has been so widespread that beating is in fact now practically the reserved privilege of the English upper classes. Dr. Shrubsall ascribed the establishment and maintenance of corporal punishment in our public schools to the two great influences that governed literary minds at the time of the Renaissance. In Greece and Sparta boys over 7 were sent to boarding school, where there was a prefectorial system, and the elder boys whipped the younger. They were also organized into raiding packs to train them for war, and suffered punishment for idleness or inefficiency from their seniors as well as from adults. Everyone is familiar with the biblical passages which encourage the stern father, but Dr. Shrubsall pointed out that in the original Hebrew "rod" meant "sceptre" and "chasten" might be used for "instruct." The idea behind the Hebrew advice was definitely that of training. As Dr. Shrubsall emphasized, punishment must never be vengeance; the "I'll larn you" type of punishment may have serious and unexpected consequences. The whole idea underlying punishment of any kind must be to fit the child for the world in which he is to live. Even a convinced anti-punishment expert has admitted that he would smack a child who persistently ran into the road, the risks being too great for milder methods. Dr. Moodie urged the necessity for impressing parents with their responsibilities, and among the first of these responsibilities must be that of giving the child the easiest possible introduction to the inevitable knocks and buffetings of the world he lives in. If a smacking is better than being run over by a car it is probably also better than the unthinking cruelty meted out by his fellows to the small boy who has never learnt in the nursery how to respect other people's rights. The natural way of learning for children as well as for animals is through immediate dermal stimuli. The burnt child dreads the fire because it early forms a strong association between fire and pain. In the same way the toddler learns to avoid hard objects which bruise it. In the social and psychological sphere, however, the effects of bad habit may be delayed, and it is clear that the parent should step in to form those associations which he believes will, in later life, save the child from pain. Dr. Shrubsall emphasized the uselessness of delayed punishment and the danger of threats and scoldings, which may do infinitely more harm to the nervous system than a spanking given at the time and so associated firmly in the child's mind with the offence. Far more children have been permanently harmed by threats of bogies and policemen than by corporal punishment. Moreover, psychologists are agreed that the one thing which must be avoided in early life is the production of any serious doubt in the child's mind of the security of the home and of parental affection. The child understands quite well a blow given in anger, but may be seriously alarmed by solemn reasoning and the futile threat: "If you do that, mother won't love you any more."

SCIENCE ON EXHIBITION

For more than twenty years the Physical and Optical Societies have combined in an annual exhibition. The Optical Society has now amalgamated with the Physical Society; but, although the name "optical" no longer appears, optical instruments were as well represented as ever in the display which was shown at the Royal College of Science, South Kensington, during the first week of the new year. For the ophthalmologist there was the usual array of testing and diagnostic instruments, together with spectacle wear, including protective lenses against infra-red radiation, to mention only one of the special devices shown. The new type of lens which is placed in contact with the surface of the cornea, and so is almost invisible, was also demonstrated. The pathologist had a bewildering choice of microscopes. The specialization of the microscope goes on apace, and some of the high-power binocular microscopes seemed to offer the last word in facility of adjustment and perfection of result. One new inverted microscope had the objective underneath the stage and the condenser and illuminant above, an arrangement permitting operation upon bacteria in a lying drop, which is a flat stratum, as compared with the centre of a hanging drop, where movement is too free and the object may be difficult to focus. Projection apparatus also embodies many new refinements. The physiological instruments included the portable cardiograph, the sphygmomanometer, a fatigue machine for studying and registering the amount of distraction due to mental fatigue or to the influence of sensory stimuli, and a device called the eupatheoscope, designed to measure and record a quantity analogous to the physical sensation induced by a cool environment, thus forming a "comfort meter" for checking the efficiency of a heating installation. All these instruments and many others in the physical and electrical field were shown by about eighty commercial firms, and illustrated the research and experiment which is always proceeding in commercial laboratories and workshops. In a special research and experimental section to which research associations and national laboratories contributed were a number of other interesting exhibits. Here Professor E. W. Scripture of Vienna again demonstrated his experimental phonetics and the graphic registration of speech. He has evolved an ingenious method of obtaining periscope films of the glottis. A very strong beam of light is thrown by means of totally reflecting prisms through a small tube, which is passed around the side of the tongue and upon the top of the larynx. The view of the glottis and the neighbouring parts is projected by lenses and totally reflecting prisms back around the tongue through another tube to the moving film of a kinetocamera. In this way it has been found that the larynx acts specifically for every sound. Each of the vowels, for example, has a different laryngeal action. Allied with this exhibit the West End Hospital for Nervous Diseases, through its speech department, showed examples of the graphic registration of speech in disseminated sclerosis, epilepsy, and general paralysis of the insane. By means of the microphone and sound camera the patient's speech is regis-

tered also as a sound track on the film, and the exhibit included the sound track of speech in disseminated sclerosis, the first ever made of speech in a nervous disease, with the characteristic irregularity of the waves produced by a puff from the glottis in producing the tone of the voice. It is contended that this is a method of diagnosis in cases of nervous disease affecting speech as specific as a sugar test in cases of diabetes. One of the exhibits of the National Physical Laboratory illustrated an interesting piece of work on the luminous efficiency of rays entering the pupil at different points. It is commonly assumed that the apparent brightness of an object is proportional to the pupil area of the observing eye, but in this work a photometric match had been made between two fields, one illuminated by rays entering the eye axially and the other by rays entering the eye at any desired point of the pupil opening. It was found that for a ray entering the eye near the periphery of the extended pupil the luminous efficiency is only about one-third that of an axial ray.

VASCULAR RESPONSE TO HEAT AND COLD

An interesting contribution to the study of vascular reactions to heat and cold has recently appeared under the names of Th. Brosse, J. Levigne, J. Mage, and A. van Bogaert.[1] These workers have apparently been able to formulate by means of a simple hot-and-cold-bath technique certain tests whereby the state of the arterial and capillary walls may be indirectly ascertained. The varying results which had previously been reported as the result of the employment of such simple stimuli as heat and cold led them to start their work on a small series of healthy control subjects, in order that the normal physiological response might be thoroughly understood. Subsequently, a larger group of patients with thickened and tortuous arteries were subjected to the same procedure and the results compared. The evolution of the technique of their hot-and-cold-bath test, before a standardization was evolved which would enable the observers to allow for such incidental complicating factors as temporary variations in the blood pressure and in the rate and amplitude of the heart beats, is discussed at some length and repays study. The investigation of the pathological group was concerned not only with the larger arteries, but also with the end arterioles and capillaries. For the larger branches of the arterial tree oscillometric records were taken of the amplitude of the arterial pulsations, while in the latter cases more delicate investigations into the alterations in the capillary diastolic pressure and the skin temperatures were pursued. The technique and safeguards employed are described, and show considerable ingenuity. The importance of using the double (hot-and-cold) test in all instances is stressed, owing to the fact that an apparently normal artery, which subsequently gives evidence of disease, will often give identical responses to either stimulus. It was found that in young normal subjects local immersion in a hot bath (42° C.) increased the amplitude of the arterial pulsations, particularly at levels approaching the diastolic, while the diastolic pressure itself was, in the majority of cases, lowered. With the subsequent application of cold (7° C.) to the same individuals the arterial pulsations were seen to be decreased in amplitude at all levels, whilst the diastolic pressure was raised from the normal level to a varying extent. In certain cases in which the diastolic pressure was much raised, however, the amplitude, after prolonged immersion, was seen to be increased at those levels immediately below the systolic. In the arteriosclerotic group, contrary to expectation, the reactions were in most instances superficially similar to those given in the normal group. As the result of their experiments, however, the authors tentatively describe an "arterio-capillary reaction to heat and cold" from which, they claim, the anatomical state of the walls of the arterial system may be estimated. They assert that many cases of apparently subjective phenomena of the extremities will be found to have their basis actually in early organic disease of the arterial walls. They emphasize that it is unsafe, however, to make other than *qualitative* deductions from the tracings obtained in such instances. Sir Thomas Lewis has done much, by his recent work on the capillaries, to redirect the attention of young physiologists to that simple type of clinical research for which England was at one time remarkable. There is still much scope for the type of investigation outlined above, and the modern revival of interest in hydrology as a useful although neglected "handmaiden of therapeutics" would seem to point to the present time as being propitious for its accomplishment in certain spheres.

RADIOTHERAPY IN HYPEREMESIS

The severe vomiting of pregnancy has been treated by almost every drug known to medicine with varying degrees of success. There seems little doubt that a psychical factor plays a large part in many, if not all, of the cases, so that the ever-ready taunt of "suggestion" can be applied to any new treatment recommended. Nevertheless, the action of radiotherapy, as recently recommended by Dr. E. Speder,[1] seems to deserve further investigation. He has treated only nine cases, but he meets the accusation of having produced his results psychologically by pointing out that his patients had previously had far more dramatic and suggestive treatment without effect; that in many cases they did not know they were being treated, but thought the rays were being applied diagnostically; and that one and all showed a curious recrudescence of symptoms between the fifth and seventh hours and an amelioration between the twelfth and twenty-fourth hours after treatment. All were relieved of the vomiting, and showed a normal pulse rate, blood pressure, and urine volume within forty-eight hours. The consistency of results is against a purely psychological explanation. Dr. Speder's method of treatment is to irradiate the dorso-lumbar region over a field 20 cm. in diameter with rays at 95 kV with a moderate filtration of aluminium. His explanation of the success which he achieved in all nine cases is that the intractable vomiting is due to a disturbance of the neuro-vegetative system. He puts forward his hypothesis quite tentatively, and appeals for further study of the subject; but he suggests that the radiation of the back has a regulatory effect on the large abdominal centres of the sympathetic system. The adoption of this method of treatment obviously calls for considerable care, in view of the fact that the application of

[1] *Bull. et Mem. de la Soc. de Radiol. Méd. de France*, 1932, xx, 505.

x rays has been known to produce abortion. Indeed, it has recently been recommended as a therapeutic agent for this purpose. W. Harris[1] found that a 60 per cent. skin erythema dose given into the gravid uterus produced a satisfactory expulsion of the foetus in 129 out of 138 patients. Usually two fields were sufficient, but one obese woman required six. He recommends the method for patients in whom surgical intervention is undesirable—for instance, tuberculous, cardiac, diabetic, and epileptic cases, and those with pelves severely deformed by arthritis. The exact mechanism underlying the death of the foetus is not clear, and abortion can be brought about without sterilization. It may be argued that a woman suffering from intractable vomiting is in such a bad way that the risk of abortion is a justifiable one to take, or it may be that careful investigation will reveal a technique which cures the vomiting without exposing the foetus to any harm. Certainly the use of *x* rays both for the treatment of vomiting and for the induction of abortion merits further trial.

STORAGE OF FOOD

The Department of Scientific and Industrial Research has issued Part I of the fourth volume of the *Index to the Literature of Food Investigation*.[2] It must be obvious to everyone that the question of storage and distribution of food is a most important one for modern civilization. Food must be preserved for use in the unproductive times of the year, and must be brought from the producing countries to the crowded populations of the industrial countries. Moreover, it is plain in the light of modern knowledge that food must be stored in such a way that its nutritional value is as far as possible preserved. While these facts are well recognized, it is still difficult for anyone not closely concerned to realize the large variety of problems confronting those engaged in the handling of food. For this reason Miss Glennie's introduction to this volume is of the greatest interest. It speaks briefly of the progress made in many branches of storage, ranging from engineering problems of large-scale refrigeration to the condensing and sterilization of milk or the estimation of vitamins in tinned tomatoes. Cold and gas storage of fruit for transport, the avoidance of discoloration or metal contamination in cheeses, and the preservation of fats by hydrogenation are all subjects of practical importance; while the more academic knowledge of the biochemical processes taking place in excised muscle, or of the injury caused to the colloidal systems of the cell by freezing, is here applied to practical purpose. It is to be hoped that the type of work described here will eliminate the terrible wastage caused by fluctuations in the supply of foodstuffs hitherto regarded as perishable. In respect of the actual abstracts of original works contained in this volume, it could perhaps be urged that when possible the conclusions arrived at by the authors should be stated. Many of the abstracts merely describe the problem investigated, which is enough when reference to the original papers is easy but otherwise not very satisfying.

STANDARDS OF X-RAY DOSAGE

The special supplement to *Acta Radiologica*, by Dr. Robert Thoraeus,[1] consists very largely of a description of the ionization chamber to be used as standard for the measurements of *x* rays in Sweden. It is designed in accordance with recent research into the properties of such chambers, exact specification of experimental detail of both *x*-ray plant and measuring apparatus being included. The limits of accuracy are carefully discussed, and it is reported that an accuracy of plus or minus 1.5 per cent. is obtainable in the specification of the *r* unit. In addition, the absorption of standard *x*-radiations in copper, tin, silver, lead, and water are discussed and results are given, while a fairly detailed description is included of the secondary aluminium chamber which has been used for some time in the calibration of therapeutic *x*-ray outputs throughout Sweden. Some interesting observations are made on the so-called equality of filters of different metals, these remarks leading to a detailed description of Dr. Thoraeus's well-known tin filters for therapeutic use. The water phantom measurements which he gives are clearly preliminaries to a more complete study of the problem. While containing little that is fundamentally new, this paper is of considerable value as being a description of very carefully controlled experimental arrangements as standards of *x*-ray dosage. The data relating to filters will be particularly useful for reference purposes in therapy.

SIR CHARLES HASTINGS LECTURE

The fifth of the series of Sir Charles Hastings Lectures, inaugurated by the British Medical Association for the purpose of offering to the public information by the highest authorities on matters of general public interest, will be delivered in the Great Hall of the Association's House in London on Tuesday evening, February 21st. This year's lecturer is Sir Henry Gauvain, medical superintendent of the Lord Mayor Treloar Cripples' Hospital and College, Alton, Hants, and his subject will be "Sun, air, and sea-bathing in health and disease." The chair will be taken at 8 o'clock by the President of the Association, Lord Dawson of Penn, and after the lecture relevant questions in writing are invited. Admission is free, by tickets obtainable on application to the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by ticket-holders by 7.50 p.m. will be available for other members of the public.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been prepared and will be ready shortly; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a post-card notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1.

Ireland

The Irish Committee and the Irish Medical Committee

At a meeting of the Irish Committee, held in Dublin on December 20th with Dr. W. W. Murphy in the chair, the President-Elect, Dr. T. Gillman Moorhead, gave a detailed account of the work that was being done in connexion with the preparations for the Annual Meeting, and of his recent visit to Belfast. He assured the committee that the profession in the northern capital would do everything in its power to make the Annual Meeting a success. The committee discussed at considerable length sixteen items on the agenda of the Irish Medical Committee.

A meeting of the Irish Medical Committee was held in the afternoon. A resolution from the County Limerick Local Medical Committee recommended the federation of the Irish Medical Committee with the Irish Medical Association. It was, however, decided unanimously that the former should continue, and that the Irish Committee of the British Medical Association and the council of the Irish Medical Association should receive a special representation, and should be invited to send two representatives from each body. Without the provision of this special representation the Irish Medical Committee is constituted almost entirely of the most active members of the two associations. It was also decided that applications from other medical bodies seeking representation on the Irish Medical Committee should be considered. The committee approved the resolution from medical practitioners in Cork in regard to insured patients and their dependants, or other patients admitted for treatment to voluntary general hospitals, that the medical attendant shall reserve the right, so far as is consistent with the rules of the hospital, to charge for his attendance when he is satisfied that the patient concerned can afford to pay. A motion from Cork Dispensary Doctors' Association, advocating the formation of a National Association of Dispensary Doctors, with county branches, was deferred pending certain developments, and a motion from County Cork Dispensary Medical Officers' Association, dealing with the treatment of private patients in district and county hospitals, was considered and referred to the executive committee. The recent order of the Dublin Board of Assistance to dispensary medical officers, requesting them to issue certificates without fees to school children, was considered to be *ultra vires*. The question of fees for certification of births, deaths, and marriages was discussed, and it was decided to draw the attention of the Registrar-General to the inadequacy of the fees at present paid in the Irish Free State. A resolution from the council of the Irish Medical Association, protesting against the Government's new procedure when filling medical vacancies, was carried by eight votes to three. Previously the name of the first candidate placed on the list by the Selection Board was sent; now a panel of three names, in alphabetical order and without any indication of order of merit, is forwarded to local authorities, giving them the permission to elect any one. An amendment, moved by Dr. Butterly (Louth) to the effect that there was "no particular objection to the changed method, as it gives a better chance for local knowledge, affiliations, and compatibility, and hence a greater public confidence in professional duties and doings," was lost. The question of the erection of residences by local authorities for their medical officers, and of suitable dispensary houses for the treatment of the poor, was discussed; it was agreed that these matters should be brought to the notice of the Minister for Local Government and Public Health. It was also decided to draw the attention of the Minister to the question of promotion or transfer of medical officers under the Local Authorities (Officers and Employees) Act, 1926, and of the recognition of their previous services in the different health areas in the Free State. It was approved that a suggestion should be made to the Minister that the Irish Medical Committee, Irish Medical Association, and the Irish Committee of the British Medical Association should be invited to give advice as to the personnel of the forthcoming commission on hospital policy, and that in future the Irish Medical Committee should be consulted in all cases where advice is sought with regard to medical legislation, thereby avoiding unauthorized representations. In regard to fees payable under the Coroners Acts, the following resolution was carried unanimously: That the attention of the Minister for Justice be drawn to the injustice of compelling medical practitioners to attend at several adjourned inquests and only receive one fee; that it is considered inequitable that no fee is allowed for a coroner's inquest or inquiry on patients dying within public institutions; and that, where the doctor performing the post-mortem examination considers assistance necessary, it is advisable to call in a second medical man. Finally, it was decided that the necessity for amendment of the Local Government Act, 1925, in the matter of pensions should be brought to the notice of the Local Government Department. The subject of the overcrowding of the medical profession was deferred to another meeting.

Scotland

Stirling Royal Infirmary

At the annual meeting of subscribers to Stirling Royal Infirmary Professor D. P. D. Wilkie of Edinburgh said there had been a great change in the policy of voluntary hospitals in recent years. Although these hospitals had started as charitable institutions for the sick poor they were no longer in this category: they provided medical and surgical assistance for nearly 85 per cent. of the total population. This meant that the public were demanding efficient hospital service and were prepared to pay for it according to their means. It was the duty of hospital authorities to provide this service; it was their duty to provide hospital accommodation for that class of society, the "black-coated" class, which deserved the fullest consideration, but which had not received fair play hitherto in the matter of hospital services. The people of this class had always been good citizens; many were unable to afford nursing homes, and they did not like to enter hospitals on the basis of getting something for nothing, though they would willingly pay for their maintenance and treatment if hospital managements would provide small wards or rooms. If the voluntary hospitals were not prepared to take this matter up the municipalities or the State would step in and do so. He believed in the voluntary system, by which he meant voluntary management of hospitals: more efficient service and more sympathetic knowledge of the needs of the community could be obtained from it than from municipal or State management. The chairman, Colonel Dundas, said that the past year had seen the development of the new contributory scheme for treatment; this had been a great success. They should hold on to the voluntary system, but at the same time it was important that they should work in close co-operation with the local authorities, and he was glad to report that during the year they had been able to clear up some financial questions of considerable difficulty. The position of the hospital was better than that of a great many others, but they must not relax their efforts. The annual report showed that the number of patients treated in the wards had been 2,402, and the average daily number 130. The

income of £14,738 represented an increase of £409, but as the expenditure had been £16,181, there was a deficiency on the year's working.

Health Visitors

A memorandum issued by the Health Department states that the examination for the health visitor certificate will in future be conducted by the Royal Sanitary Association of Scotland under regulations approved by the Department. It will be available to any registered nurse who is a certified midwife and who has completed an approved whole-time course of training for health visitors of six months. The issue of certificates by training institutions will be discontinued. Courses have been approved at the department of social study and training of Edinburgh University and at the school of social study and training at Glasgow University. They have been organized in co-operation with the public health departments of these two cities, and have been adjusted with a view to giving thorough theoretical and practical instruction in the duties which health visitors have to undertake under the local authorities in Scotland as well as for appointments in England and Wales. The course and the certificates to be issued have been recognized by the Ministry of Health in England.

England and Wales

A Hospital for Lilliput

Last week the Prince of Wales, as president of the King Edward's Hospital Fund for London, visited the Building Centre at 158, New Bond Street, and on behalf of the Propaganda Committee of the Fund declared open a scale model of a modern hospital. The idea of the construction derives from the Queen's dolls' house, and the completeness of this piece of work down to the smallest detail is astonishing. On a scale of three-quarters of an inch to a foot it represents a three-floored hospital, with wards, operating theatre, *x*-ray department, balconies, and garden, with minute figures for doctors, nurses, and patients. Every window has its independent metal frame, every door its rebated lining fitted to the opening to which it is hinged. The electric wiring is carried in cavities through the teak-boarded floors. For the exterior, a brick-like face has been provided, indicating about a million bricks and seven thousand stones. An ambulance entrance, with a sloping way for stretcher cases, has been put in; the motor ambulance is also there. There is a bed lift in its well, the car constructed in steel, finished with cellulose, and supported on a frame with safety gear below; the lift travels at the rate of ninety inches a minute, and operates on a supply of 6 to 8 volts. The metalwork in the board room is in ornamental bronze, the carpets and curtains have been specially made by the Royal School of Needlework, and four miniature portraits hang on the walls, being those of Florence Nightingale, Lord Lister, Lord Dawson of Penn, and Lord Moynihan, all by Mr. Alfred Praga, the president of the Society of Miniaturists. Even the minute book for the board room has not been forgotten. The *x*-ray department is a perfect reproduction in miniature, with an up-to-date equipment for the screening room, the radiography room, with dark room adjoining, laid out with all the materials for the photographic process; and beyond this is the *x*-ray treatment room, with cubicles fitted with windows of ray-proof glass. In the ward the twelve beds are divided by glazed screens, and the beds are complete with castors, springs, mattresses, blankets, and linen. At the end of the ward is a solarium, designed to secure the maximum amount of sunlight. Off the corridor open bathrooms and lavatories, with sanitary fittings to satisfy the most fastidious. The two operating theatres have a combined sterilizing and washout room between them. The theatres are illuminated by shadowless light. The hospital kitchen is completely equipped for steam, gas, and electricity. In fact, in a model which can be easily accommodated in a small room, there appears to be everything of which the modern hospital administrator could dream, from a grand piano to a refrigerator. There are even steel lockers for the patients' clothing, a set of fire appliances, a petrol pump, and the most modern lighting equipment. It has not been possible to include an out-patients' department, a laboratory, a laundry, or a nurses' home; these only must be left to the imagination. Lord Burnham, addressing the Prince of Wales, referred gratefully to the many firms and professional and private people who have contributed to the furnishing and equipment; and the Prince of Wales expressed his delight and congratulations, and the hope that many who had had no occasion or opportunity to inspect the interior of a modern hospital would see the model and so learn what countless services a hospital performs, and incidentally gather some idea of their costliness.

Residential Treatment of Tuberculosis

At the present time residential treatment is provided by the London County Council for tuberculosis patients either at the Council's own tuberculosis hospitals and sanatoriums or at voluntary sanatoriums, under the arrangements prescribed in the Council's scheme for the treatment of tuberculosis in London, or in the public general hospitals recently transferred from the boards of guardians. The tuberculosis scheme originally made by the Council in 1922 excluded from its operation tuberculosis patients who were receiving treatment under the Poor Law, but the residential treatment of both classes of tuberculous patients is now the responsibility of one authority only—namely, the London County Council—and the Council has decided that the time has come to arrange for all classes of cases to be dealt with under the one tuberculosis scheme. It is felt that there is no reason for preserving the distinction in respect of residential treatment of cases under the tuberculosis scheme and those in the transferred general hospitals. The arrangements for dealing with cases have already administratively been merged to a considerable extent, with satisfactory results, and it has been found possible with a united service to allocate the accommodation available to much better advantage than when the cases were classified in separate categories. In November last the Council expressed the opinion that the review of assessments of contributions towards the cost of treatment under the tuberculosis scheme should be undertaken by the Public Assistance Committee, and the Minister of Health has been asked to amend the scheme to give effect to this arrangement. The Public Assistance Committee was already dealing with the assessment of tuberculous patients in the general hospitals. It is part of the arrangement that all assessments will be made, in the first place, subject to review, by the Tuberculosis Care Committees. These changes, both as regards dealing with all cases under the tuberculosis scheme and as regards assessment, will operate as from April 1st next.

The Northcote Trust

An interesting record of social service for hospital in-patients is to be found in the twenty-third annual report of the Cicely Northcote Trust, which covers the period October, 1930, to October, 1931. The trust, which came into existence in 1909, now forms an integral part of St. Thomas's Hospital, and extends the work of the almoners from the out-patient department to the wards. Its main objects, as with medical work, are to prevent ill-health, to alleviate suffering, and to cure disease. It must ensure that the benefits of treatment are not nullified

by a patient's too sudden return to work, by lack of proper food, or by unsatisfactory home conditions. This involves multifarious activities, which include the provision of extra nourishment, instruments, and appliances; the arrangement of special treatments; and the placing of patients in suitable homes, sanatoriums, lodgings, and spas. Assistance is provided in respect of ambulances, railway journeys, invalid chairs, and even of ward lessons. Three special branches of work exist for the benefit of diabetics, cancer patients, and young girls suffering from venereal disease. Insulin, even at the reduced hospital rate, is not cheap, and financial assistance has frequently to be given to uninsured patients. In addition to this, advice is offered in respect of diet, mode of life, etc. Those suffering from malignant disease have to be watched, visited, and provided with extra comforts and help, while arrangements are necessary for admission to special homes. The Northcote Trust Hostel, which watches the interests of the more unfortunate victims of venereal disease, was opened again during the year under review, and admitted forty patients. The "Fathers and Mothers Club," at 37, Royal Street, S.E., serves to supplement the work of the hospital maternity department and to strengthen the bond between patient and hospital.

CORRESPONDENCE

Principles of Obstetric Practice

SIR,—Dame Louise McIlroy, in her article on the above subject, expressed the opinion that the doctor who is to be in attendance at a confinement should, if possible, conduct the ante-natal examinations, and Dr. T. G. Robinson has emphasized the importance of this point in midwifery practice in his letter to the *Journal* of January 7th (p. 40). It is, indeed, generally recognized.

It cannot be too widely known that this was also the view of the Maternal Mortality Committee (Interim Report, p. 68; Final Report, p. 32), who were fully acquainted with the disadvantages of the divided responsibility arising from ante-natal clinics. It is, however, doubtful whether Dr. Robinson's somewhat crude method of compelling women to attend their doctor for ante-natal care would prove effective, and even if it did, extensive alterations in the provisions of the National Health Insurance Acts would be entailed. There is little doubt that when the necessary financial arrangements for a national maternity service can be made every expectant mother will be enabled to put herself under the care of the doctor of her choice during pregnancy without expense to herself.

In the meantime a good deal can be done to implement the advice of the committee on this point. The position is briefly as follows. Shortly after the issue of the Interim Report of the Maternal Mortality Committee, the Ministry of Health circulated a memorandum to all maternity and child welfare authorities authorizing them, *inter alia*, to make arrangements whereby private medical practitioners should be enabled to undertake the routine ante-natal examinations of uninsured women who have engaged midwives for their confinements. This was to apply not only in rural areas but also in towns, to meet the needs of those women who are reluctant to visit an ante-natal centre. If this advice were taken it would constitute a step in the right direction, but under our system of local government the Ministry of Health has no power to enforce these views, and therefore local action is necessary to supplement it. Only a few authorities have made a beginning with such a scheme, the usual reason for not doing so being given as financial stress. Many local authorities and medical officers of health, however, appear to take an exaggerated view of the usefulness of publicly provided clinics, and are blind to their limitations and disadvantages; it is therefore incumbent upon Divisions of the British Medical Association which wish to obtain these facilities to take the initiative. As they would be acting in accordance with the views of most authorities they would have a very good chance of success. Any Division which decides to do so should first obtain a copy of the Final Report (Adastral House, Kingsway, London, W.C.2, price 2s. 6d.), which contains a large amount of information together with a verbatim copy of Memo. 156 and a form of ante-natal record suitable for use in such schemes.—I am, etc.,

Poplar, E., Jan. 8th. W. H. F. OXLEY.

Death under Spinal Anaesthesia

SIR,—As a rather ardent advocate of spinal anaesthesia, and especially of that induced by percaine, I feel it only proper to record a death under this type of anaesthesia—even although it is my conviction that the particular drug used was in no way responsible.

The patient was a man of 84, suffering from complete intestinal obstruction, which was found to be due to a band from an old appendicitis. One lung was in a condition of bronchiectasis, and the pleural cavity of that side had been the site of an empyema which was treated successfully by aspiration a year ago. He had copious faecal vomiting, and was considerably distended. In these circumstances the choice of anaesthetic was a difficult one. General anaesthesia appeared to be contraindicated on account of the state of the lungs, and local anaesthesia in view of the distension of the abdomen, combined with the necessity for rapid operation owing to his age and serious condition. He was given 11.5 c.cm. of 1/1,500 percaine solution at 4/5 lumbar, which enabled the operation to be performed with speed and facility. At the finish his condition was poor, but improved so considerably after a gum-saline infusion and injection of pituitary extract that I felt the immediate result was no longer in doubt. Twenty minutes afterwards he suddenly had a very large faecal vomit, and, despite the fact that he was in a partial Trendelenberg position and vigorous endeavours to clear the pharnyx, he literally drowned in his own vomit—a quantity of which was found in the one working lung at necropsy. He was evidently at such a low ebb and his laryngeal reflexes so inactive that he could make practically no effort himself to avert the catastrophe.

There may be reasons for criticism of the surgical conduct of this case, but for the moment I am concerned solely with the anaesthetic side of the problem. At the Centenary Meeting I expressed the opinion that the chief contraindication to spinal anaesthesia in abdominal cases was in old people with intestinal obstruction. The present case seems to support this contention; indeed, the only deaths I have had in an experience of about 3,000 spinal anaesthetics have been in three such cases—one with novocain, one with stovaine, and now one with percaine. In all cases death was preceded either by a massive action of the bowels or by a copious vomit, and, while some may regard this as a terminal event, the condition of the patients immediately before did not suggest this, and I believe that the sudden loss of a large bulk of fluid from the abdomen has an effect similar to the collapse which is sometimes seen in the aged after such a simple action as the return of an enema. A sudden fall of blood pressure is the accepted explanation of these cases, the inelastic vascular system in old age being unable to accommodate itself rapidly enough to sudden changes in a portion of the peripheral circulation.

The effect will obviously be enhanced in the presence of spinal anaesthesia, but here it must be pointed out that the maintenance of the blood pressure and the constant adjustments that are required to keep it within normal limits are dependent not solely upon the vasomotor nerves; the rate of the heart, and its output, are also important factors. For complete control, therefore,

in addition to the vasomotor nerves, the inhibitor and accelerator fibres to the heart and the nervous control of the suprarenals, and perhaps of other endocrine glands, must be intact. Under spinal anaesthesia a portion of the vasomotor control is cut off, but with low anaesthesia the fibres to the heart are not interfered with, and the maintenance of the blood pressure is partly a compensatory effect of the unaffected vasomotor nerves and partly a regulative alteration in the heart rate and output. With high spinal anaesthesia, however, some of the sympathetic fibres to the heart may be cut off, as also may those to the adrenals. Thus the balancing mechanism is trebly disturbed. Under unbalanced vagal action the heart beats slowly and the total output is reduced. This, combined with widespread vasomotor paresis, accounts for the fall of blood pressure—a fall which may often be surprisingly small, a fact possibly due to the development of a local automatic response in the vessels, or perhaps to a delayed adrenal response in the absence of nervous control. In the aged it is probably these latter mechanisms which fail, and the effect is increased by the circulating toxin in the blood in cases of intestinal obstruction.

The fall of blood pressure under spinal anaesthesia is a phenomenon which is attracting a lot of attention at present, and for which many diverse explanations have been forthcoming. The majority of these concentrate upon one aspect and fail to recognize that the maintenance of normal blood pressure is a many-sided mechanism of considerable complexity (too complicated indeed to be considered at length in a letter), and that the administration of a high spinal anaesthetic dislocates this mechanism in many more ways than by simple interference with vasomotor nerves.—I am, etc.,

London, W.1, Jan. 8th.

Rheumatic Fever and the Tropics

SIR,—With regard to the correspondence in the *Journal* on the above subject I would point out that no part of the Punjab is inside the Tropics, and that Nairobi is above sea-level; but the letter of Dr. M. Mackinnon is of much interest, as some change apparently has taken place in the highlands of that part of the world, and a similar change may have taken place in Malaya at a low elevation. Dr. Neave Kingsbury writes of two definite cases of rheumatic fever, and Dr. Wallace of one case of rheumatic fever and one of chorea, which have occurred in Kedah in natives of India. In these two tropical countries I think it is certain that rheumatic fever formerly did not occur, but now seems to be found. In each of these countries there has been a large increase in the European population; and, owing to the increased rapidity in rail and shipping communications, there is now a greater chance of an infected man or animal getting through the Tropics from Europe.

It has lately been shown that in certain overcrowded institutions haemolytic streptococci in the throat may be closely associated with outbreaks of exacerbations of the manifestations in rheumatic hearts. Coburn has shown that there is a definite positive correlation between the seasonal distribution of haemolytic streptococci and rheumatic fever. The seasonal conditions mentioned are those of the spring in New York, and these are difficult to bring into line with climatic conditions of the Tropics, even at high elevations. Haemolytic streptococci, according to Coburn, are not often present in the flora of the pharynx in the Tropics, and, if found, quickly disappear, the disease process rapidly becoming quiescent. In fact, transfer to the Tropics seems to be the best though, unfortunately, an expensive treatment for rheumatic fever. Dr. Coburn says that his findings suggest that unhygienic conditions favour both the activity of the haemolytic streptococci in the throat and the incidence of rheumatic fever. I cannot, however, think that the *Streptococcus haemolyticus* is the only infective agent.

There is much that requires explanation. A haemolytic streptococcal sore throat may get perfectly well and the organism disappear, but ten to twenty-one days later the heart may show signs of being seriously affected. The worst manifestations of the disease take place at a time when the organism is found in neither the throat nor the blood. It is not easy to understand how haemolytic streptococci, which may occur as secondary invaders in almost any infectious disease, can be regarded as the primary cause of a disease so obviously specific. It is difficult to understand how the different manifestations of rheumatic fever can result from a soluble poison produced in a single small focus. The continuing scar formation in the heart valve is also difficult to understand, unless the source of the infection is constant.

But Ledingham writes that in some virus diseases there may be concomitant bacteria, and a *Bacillus proteus* X of the Kingsbury strain has been found in the urine in a case of tropical typhus. Is it not possible that a virus in association with a strain of haemolytic streptococcus may explain some of the mystery of rheumatic fever?—I am, etc.,

J. TERTIUS CLARKE,
Late Medical Officer and Health Officer, Perak, F.M.S.

Harrow, Jan. 7th.

SIR,—I have read with interest the correspondence on this subject, and I can say that I most strongly endorse Colonel Hughes's letter appearing in your issue of December 31st, 1932. After twenty-eight years in India, most of it spent in a province south of the Punjab—namely, Bihar and Orissa—at Patna, my experience shows that cases admitted to the wards for acute rheumatism and rheumatic endocarditis, chorea, etc., were quite numerous during the cold weather. These cases were typical of acute rheumatism, etc., and reacted to the appropriate anti-rheumatic treatment. Many children were admitted to my wards with typical rheumatic endocarditis, which developed into mitral stenosis—proved in several cases by post-mortem examination later—and a considerable number of cases of acute chorea were admitted and cured by anti-rheumatic treatment only. There is no doubt whatever in my mind that acute rheumatism with endocarditis is almost as common in India during the cold weather—in those provinces which have really cold weather—as it is in any country with a temperate climate. I also fully endorse Colonel Hughes's views regarding aortic lesions, which I have found to be as frequently rheumatic in origin as syphilitic.—I am, etc.,

H. R. DUTTON,
C.I.E., F.R.C.P., Lieut.-Col. I.M.S. (ret.),

Epidemiology

SIR,—As Sir William Hamer has quoted one immortal character from a novel I may quote another, the Rev. Dr. Folliott, who once observed, "There is good and sufficient reason for the fig being barren, but it is not therefore the less a barren fig." Sydenham said that the same fevers, especially the continued fevers in different epidemic constitutions, needed totally different treatments. Freind remarked that "if we consider the method which this writer has adopted in curing these fevers of, as he says, utterly different types, a method in which he was eminently successful, we shall find no trace of this dis-

tinction." Sir William challenged this statement. I then gave a list of all the passages in the *Medical Observations* known to me in which Sydenham gave details of his treatment of continued fevers. Sir William gently censures me for not quoting a passage which does not describe *any* method of treatment, and has been adequately summarized by Greenhill in the words: "Ubi nondum constat, quid sit agendum, nihil agendo et Medico et aegro optime consulitur." Freind's point is that, "ubi constat, quid sit agendum," Sydenham's agendum is always the same. To confute him one must show that the agenda of the passages I have quoted or of some passages I have missed *are* really different. It is a purely clinical problem. Freind thought that the doctrine of epidemic constitutions had little or no clinical importance, and that it did not effectively influence Sydenham's practice as a clinician. Was he right? I think only a practising physician who has studied Sydenham's writings carefully can answer that question; I certainly cannot.—I am, etc.,

Loughton, Jan. 7th. MAJOR GREENWOOD.

Dosage of Tuberculin

SIR,—Dr. John R. Gillespie's attack on haphazard dosage in tuberculin treatment in favour of a system of geometrical increases was one of the notable incidents of the session of the Centenary Meeting devoted to "The position of tuberculin to-day." The principle of geometrical or proportionate increase of dosage, to which Dr. Gillespie has so vigorously drawn attention, has an interesting correspondence to the law known in physiology as Weber's law.

"The smallest change in the magnitude of a stimulus which we can appreciate (through a change in our sensation) always bears the same proportion to the whole magnitude of the stimulus. It should be stated, however, that this law holds good within certain limits only; it fails when the stimulus is either above or below a certain range of intensity." (Foster's *Physiology*, fifth edition, p. 1211.)

Though subject to interference, this basic principle is applicable to tuberculin treatment often for long unbroken stretches of the way—a welcome guide over difficult ground. Its announcement and clear recognition are alone sufficient to rescue the session from any charge of futility, quite apart from the matter of large dosage to which Dr. Wilkinson has so pertinaciously drawn attention, and which he has punctuated, in your issue of December 31st, 1932, with the report of an interesting conversation with Koch on the subject; and apart, also, from the official report of Dr. James Watt, the publication of which in detail is awaited with much interest.

"Science is measurement." This is peculiarly true of the administration of tuberculin. But let us remember words, well worth remembering, of John Goodsir, sometime professor of anatomy in Edinburgh, which he was wont to address to his assistant: "Now, Mr. Stirling, let us have God's truth in the measurements. God's truth in everything; I live for that."—I am, etc.,

London, S.W., Jan. 8th. ROBERT CARSWELL.

*** We have received for publication a further letter from Dr. W. Camac Wilkinson, director of the Tuberculin Clinic, Nottingham Place, W., and letters from Dr. W. Bruce Fry and Dr. J. Gordon Hume, assistant physicians to the same institution. The burden of all three is the same—namely, that tuberculin given in large doses *secundum artem* is the best remedy for advanced cases of chronic tuberculosis of all forms, and is free from danger; and that to ensure success the technique, which is either that of Dr. Camac Wilkinson or a close approximation thereto, should be followed. We cannot allot more space to repetition of this point, which has been made many times by Dr. Camac Wilkinson in these columns.—ED., *B. M. J.*

"Excitability"

SIR,—My thanks are ever due to Sir Leonard Hill for his observations on my book, *Excitability*, in his letter published in your issue of December 31st, 1932, and I would now take the opportunity to make some notes which may be of interest to those engaged in medical teaching and research.

It seems to me exceedingly difficult, if not impossible, to treat of the functions of an organ without making some reference to the capacity of environmental changes to influence them. Such being the case, the next duty of an exponent should now be to decide whether the organ is rhythmically active or not, because responsiveness—the capacity of a rhythmical organ to have its activity modified by external change—so differs from the excitability studied in the muscle-nerve preparation that a rhythmical organ with much excitability has little responsiveness.

A rhythmical tissue possesses, in fact, two properties, responsiveness and excitability, whereas the quiescent members of the muscle-nerve preparation possess only excitability. Each of these properties further possesses its own laws. Thus, the behaviour of the reflex arc indicates that there is in it some structure, which may be *either* muscle *or* nerve, which is rhythmical. If, however, the presumption be made that every structure in the arc is quiescent until roused to activity by your stimulus, then the presumption plus the facts require you to seek in the arc some structure, which is neither muscle nor nerve, on which to fasten the behaviour which is not to be found in the muscle-nerve preparation. The further presumption—made like the former without positive evidence—that all fundamentals of behaviour are to be found in that preparation, leads you to the synapse theory.

The behaviour of a reflex arc really illustrates the laws of the responsiveness which is possessed by rhythmical tissues; so do also the facts of retinal stimulation by light. But if to the facts there be added the two presumptions noted above, the observer obtains the very difficult problem of attempting to explain how it can be that a rhythmical tissue can behave like a quiescent one. The problem may well seem at first sight to be insoluble, but in practice it has been proved not to be so. The literature on the eye provides theory after theory which gives an apparently reasonable solution of this really insoluble problem. The problem, however, has not been provided by the facts, but by the presumptions.

It seems to me not unlikely that many medical research workers and teachers still provide for themselves apparently insoluble problems through treating as facts of the case those two presumptions. The fact that they are presumptions should therefore always be held in view. When this is done it becomes possible to frame theories more concordant with the facts, because the observer is then free to decide whether these facts indicate that a rhythmical structure is being stimulated to greater activity or whether a normally quiescent tissue is being excited to a single outburst of activity.

The confusing of these two distinct properties of responsiveness and excitability is now general in medicine. To get rid of the confusion I have suggested that clinicians generally should cease to use the term "excitability" and employ "responsiveness" instead. That is because the phenomena they meet at the bedside seem always to follow the laws of the responsiveness of rhythmical structures rather than those of the excitability studied in the muscle-nerve preparation. They would be fairly safe, indeed, if they looked on this excitability as being more of a laboratory artefact than as a property for clinical use.—I am, etc.,

W. BURRIDGE.

London, Jan. 4th. Professor of Physiology, Lucknow.

Tabes and Naturally Acquired Malaria

SIR,—Following the publication of my short article on this subject in your issue of December 24th, 1932, I have received a communication from Dr. D. Meek of Rothes, Morayshire, which is of interest in this connexion. In the course of his experience, extending over many years, as medical officer to a group of tea estates in Assam, he can recollect at least three European planters who, although they had repeated and severe attacks of malaria at various times, yet developed tabes or neurosyphilis. The native population, however, who were saturated with malaria from infancy, the treatment of which was spasmodic and imperfect, and who suffered constantly from venereal diseases of various types, seemed to be completely immune to neurosyphilis. Dr. Meek suggests that constant saturation with malaria, combined with inefficient treatment, is responsible for the immunity of the native population.

Failure of malaria, naturally acquired, to prevent tabes in Europeans is thus further illustrated. But with regard to the native population, it seems possible that the saturation with malaria is not the only factor responsible for their escaping neurosyphilis. There may be, in addition, a higher racial resistance to invasion of the central nervous system by the spirochaete.—I am, etc.,

London, W.1, Jan. 5th. B. BUCKLEY SHARP.

Paraldehyde as a Basal Anaesthetic

SIR,—Dr. J. Duke Stewart's article in your issue of December 24th, 1932, again draws attention to the benefits of paraldehyde as a basal anaesthetic. At the West London Hospital we have used paraldehyde over a long period, and continue to use it for children—and occasionally for adults—combined with rectal ether for bronchoscopic examinations. As to its pharmacological properties, it is possibly the safest basal anaesthetic we employ.

Dr. Duke Stewart points out that the paraldehyde must be freshly mixed. As a routine at the West London Hospital a bowel wash-out is given immediately the patient leaves the theatre, and then olive oil is introduced per rectum, to be itself washed out after three-quarters of an hour. This procedure hastens recovery and guards against a possible proctitis. Perhaps it is unnecessary, but it errs on the side of safety; and it suffices to say that there has not been one case of post-operative proctitis over a period of three years. In children one drachm per stone of body weight is a safe and satisfactory formula, but our experience with adults leads to the opinion that in them this formula must be supplemented with morphine, or hyoscine as indicated by Rowbotham, if consistent results are to be obtained. With Rowbotham's technique correct dosage and consistent results can always be obtained, but the keen supervision necessary for consistent results is not always possible in busy hospital practice.

The question of fall of blood pressure and respiratory depression occurs with all the basal anaesthetics, but can be reduced to negligible proportions if the dosage and mode of administration are correct.

One rarely finds post-anaesthetic excitement with paraldehyde. Should pre-anaesthetic excitement occur it is invariably present because the anaesthetic is too light. While the margin of error between the correct dose and an overdose is wide with paraldehyde, and as a result of this it has a larger safety factor, yet I would suggest the Rowbotham method of administration as a sounder method than the empirical eight drachms for an adult weighing over eight stone. Finally, after the safety of the patient has been considered, the constancy of the result obtained is of the utmost importance when using a basal anaesthetic. Unless the individual case is closely supervised during the three-quarters of an hour before operation, paraldehyde will in adults, with greater frequency than is experienced with other basal anaesthetics, give uncertain results.—I am, etc.,

London, W.1, Jan. 4th. T. A. B. HARRIS.

Rat-bite Fever

SIR,—In a memorandum on rat-bite fever in the *British Medical Journal* of December 17th, 1932, Dr. R. A. Hickling states: "The first description of rat-bite fever in England was written by Horder in 1909." I have no wish to lead a discussion into the sterile regions of "priority" claims, but the historian of "rat-bite fever" should not omit from his bibliography the reference which occurs in a *Memoir of John Deakin Heaton, M.D.*, by T. Wemyss Reid (Longmans, London, 1883). Dr. Heaton was a successful physician in Leeds. The following extract is taken from pages 136–8.

> On the night of Sunday, December 21st [1851] "a large hungry rat . . . attacked me as I lay asleep. I was aroused by a sudden sharp pain on my nose. . . . The following morning my nose was *sore and swollen*. . . . After a few days the swelling from my nose subsided and up to Christmas Day I continued well in general health. On rising that day I had some curious giddy feelings and while at church I was chilly and uncomfortable. On returning home to dinner and while our guests were assembling I was seized with shivering and felt so sick and ill that instead of sitting down to dinner I was obliged to go to bed. This was the beginning of a serious illness. . . . I had a variety of curious symptoms in the course of the illness; a patchy eruption somewhat like Measles on my head and face, afterwards red patches very painful and tender, which became large purplish blotches from which the cuticle afterwards slowly exfoliated. I had also a peculiar inflammatory sore throat on which patches of lymph were effused and a troublesome convulsive cough and distressing attacks of dyspnoea as well as a considerable amount of general fever. Towards the middle of January I began to make some recovery and to sit up part of the day in my bedroom; but I then had much rheumatic pain and swelling in my feet, knee, and arm. On January 18th I first came downstairs. On Saturday the last day of January I left the house for the first time. From this time I gradually made a complete recovery. This illness was so singular in its commencement and progress that there were various conjectures as to its nature. Chadwick and S. Hey both attended me. The former thought I must have been poisoned by eating oysters on Christmas Eve, the evening before the attack began; the latter thought it was gout, *and there was also the question of whether it was not the result of the bite by the rat which I had received some days before.*" [Italics mine.]

—I am, etc.,

Wakefield, Dec. 23rd, 1932. REGINALD LAWRENCE.

The "Pelvic Appendix"

SIR,—Most surgeons will, I am sure, agree that delay in diagnosis, with consequent hazard to the patient's progress or even to life itself, is most frequent in those cases of acute appendicitis in which at operation the appendix is found in the pelvic cavity. The condition is doubly dangerous when of the obstructed variety. Mr. Black's recent survey of 340 cases (*Journal*, December 24th, 1932) clearly shows the still much too high mortality in this type of case. Why is it that the possession of this pelvic appendix delays diagnosis and treatment, and jeopardizes the patient's hopes of recovery? There are, I believe, three main reasons.

1. The belief is still prevalent that acute appendicular trouble is accompanied by a rapid pulse rate and a rise of temperature. While one finds that in the inflammatory type of acute appendicitis there is generally a rise of pulse and temperature, one knows from experience that, in the obstructive type especially, there is far more usually no such indication of toxic absorption until the condition

has gone on to perforation and peritonitis. If one waits for the pulse and temperature to rise, one is waiting for the appendix to perforate. Wilkie and others have stressed this extremely important point, but it is not yet fully and generally appreciated; hence the still large number of cases requiring drainage.

2. *McBurney's Point.*—At this date it seems hardly necessary to insist that a patient may be suffering from appendicular trouble although there is neither tenderness nor muscular rigidity on pressure over McBurney's point. The appendix *may* lie deep to this point, but there are many other possible positions—retrocaecal, undescended, pelvic, lying in or to the left of the mid-line; and, in the early case in which the trouble is localized, tenderness on deep pressure will be elicited *only* over the appendix. In the visceroptotic individual with constricted upper abdomen, long narrow waist, and wide pelvis, one should realize that the mobile caecum and appendix are normally situated low in the abdomen or even in the pelvis. In such a case only a digital examination per rectum (or per vaginam) will enable one to make an early diagnosis. Later, as irritating fluid—generally purulent—wells up and overflows, will tenderness and rigidity be present above the pelvic brim. Such occurs in a late case, and hence the late operation and poor result. It cannot be too often or too forcibly emphasized that tenderness and rigidity will only be elicited in the early case by pressure directly over the diseased appendix and overlying parietal peritoneum—which statement leads me to my third and perhaps most debatable point.

3. *Mackenzie's Theory.*—Mackenzie, as is well known, explained the occurrence of superficial pain and muscular rigidity in early appendicitis as due to a viscero-cutaneous and viscero-motor reflex respectively. He believed that impulses passing from the appendix by afferent sympathetic nerves to the spinal cord were "referred" to the periphery through somatic sensory nerves connected with the same segment or segments of the cord, and that in this way pain would be "felt" in the abdominal skin and not in the diseased appendix, which is insensitive to the ordinary forms of mechanical and chemical stimuli. In similar manner was muscular rigidity excited, according to Mackenzie. With this theory Mackenzie explained the superficial algesia and muscular rigidity in the *right* iliac fossa in cases of acute appendicitis, and at the same time maintained that the parietal peritoneum was insensitive. According to his theory these viscero-sensory and viscero-motor manifestations should be found in the right iliac fossa no matter what position the appendix occupied. He appears to have ignored the probability—surely one might say the fact—that being developmentally a mid-line organ the appendix is innervated from both sides of the cord, and therefore any reflex signs originating in the appendix should be found in the abdominal parietes on the left side as well as on the right.

Morley (*Abdominal Pain*) has advanced an alternative theory, to the effect that these reflex phenomena are due to peritoneo-cutaneous and peritoneo-motor reflexes, in which the nerve paths involved in the reflex are somatic only. Unlike Mackenzie he believes that the inner layer of the parietal peritoneum is exquisitely sensitive, and that it is stimulation of this membrane which is the first essential to the establishment of superficial pain and rigidity. As one who has repeated several of Morley's experiments while operating under local and spinal anaesthetics, I have no hesitation in affirming that I agree with his conclusions, and that his theory is not only more reasonable and attractive than Mackenzie's but it also stands the test of practical experience. Those who explicitly believe in Mackenzie's theory will undoubtedly miss the early pelvic appendix in which there are at first no localizing signs above the pubis.

Are we justified in assuming that any mixed somatic-sympathetic nerve reflex is probable? Can these cases of referred pain, etc., not be more reasonably explained as being due to reflexes in which the nerve paths involved are either purely somatic or purely sympathetic?—I am, etc.,

Dundee, Jan. 2nd. F. R. BROWN, F.R.C.S.Ed.

Tests for Drunkenness

SIR,—I should be very grateful to Dr. Harold Fardon were he to enumerate the tests he finds most convenient, and usually applies, for assessing the physical and mental condition of the accused.—I am, etc.,

Llandilo, Jan. 4th. J. H. LLOYD.

The Problem of Lymphoid Tissue

SIR,—I was greatly interested in Dr. J. M. Yoffey's article on the problem of lymphoid tissue in the *Journal* of December 10th, 1932, and would like your permission to add a few more proofs to the correctness of his assertion that the presence of lymphoid tissue is the real factor in facilitating the spread of inflammation and metastasis.

Some years ago, while investigating the sedimentation rate of the red blood cells in various hospital patients, I found that in every case of malignant disease the sedimentation rate was accelerated. Only in one case—namely, cancer in the upper part of the rectum—the sedimentation rate remained normal. At that time I could not find any reasonable explanation for this phenomenon, until Professor J. Fraser of Edinburgh kindly directed my attention to the recent research on the distribution of lymphatic vessels in the rectum (Villemin, Houard, and Montagne, *Rev. de Chir.*, 1925, xlix, 39). The normal sedimentation rate in this particular case was caused, in my opinion, by the relative scarcity of lymphoid tissue in the upper part of the rectum. The same fact probably explains the vast difference in the clinical picture of malignant tumours situated in the upper, as contrasted with those situated in the lower, part of the rectum. The brighter prognosis nowadays in a radical operation on a mammary cancer is due chiefly to a complete removal of all lymphoid tissue in the axilla and neighbouring regions.

Does not all this indicate that, given a method of complete blocking of lymphoid tissue, the prognosis of malignant tumours as well as of septic conditions would be far more favourable? I think that Mr. Yoffey's article is invaluable in giving a new and clear idea about the role of lymphoid tissue in man.—I am, etc.,

London, S.E.1, Jan. 2nd B. KOUNINE, L.R.C.P. and S.

The Squatting Position in Labour

SIR,—Illuminating as are the remarks of Dr. Kathleen Vaughan, there seems to be a certain lack of precision in her claims. She says that "the three things which really cause difficult childbirth are: (1) the shape of the pelvic brim, now oval, but normally round to fit the child's head; (2) rigidity of the pelvic joints; and (3) wrong position for delivery. I cannot see it at all. The ordinary oval pelvic brim is quite big enough to let the child's head through. In most primiparae it is already through before labour begins. It is when there is some departure from this normal oval that there is trouble. And the same with the pelvic joints: in a strictly normal labour they do not have to stretch at all. If they stretch, it means the pelvis is abnormal.

Her championship of the squatting position in labour is most interesting, because her findings are apparently

exactly the opposite to the traditional beliefs. She finds that the squatting position—that is, with the thighs acutely flexed on the abdomen—*lengthens* the conjugate. I wish she would tell us exactly how she came to that conclusion, because the general conception is that acute flexion of the thighs *shortens* the conjugate and *lengthens* the antero-posterior diameter of the outlet (Whitridge Williams). Hyperextension of the thighs (the Walcher position) is the posture commonly held to increase the conjugate. It is hard to believe that acute flexion and hyperextension of the thighs can both have the same effect on the pelvis. Far from Dr. Vaughan's three points explaining "everything" (her word), it seems to me that even if she is right they could only explain the small proportion of difficult labours due to disproportion. The other and much commoner causes of trouble—malpresentations, occipito-posteriors, the uterine inertias, rigidity of the soft parts, etc.—would still be there if all women had round pelvic brims, lax joints, and squatted to have their babies.

Supposing, for the sake of argument, Dr. Vaughan is right, and that all the troubles of women in labour are due to her three points, how does she propose they should set about acquiring round pelves and lax joints? If she demands only freedom from rickets and an active outdoor life, then most young women of the better-off classes have that already. The incessant activity of childhood is followed by a school life where games and gymnastics are now more of a fetish even than in boys' schools. They do not squat to defaecate, I admit, but I am sure that, in their games and exercises, they are on their hams much more often than the daily evacuations would call for. Yet I suppose their pelves are still oval. If that does not satisfy her, and she wants us all to live the lives of gipsies, canal folk, Africans, Asiatics, and New Zealanders, I am afraid we are going to keep our oval pelves to the end of time.

Any line of research which finishes with the advice to resume the habits of our remote ancestors seems to me quite unpractical, because we cannot do it; and even if we could, we would not. For good or ill, we are now a civilized and mainly urban race. If in bartering a primitive body and primitive habits for an intellect we have taken over the diseases of civilization as well, we are not going back to the jungle to look for a cure. So I fancy we are not going to be persuaded to defaecate squatting either. The attitude is alien to our temperaments, and harmonizes ill with the nature of our wearing apparel and our physical endowments, besides demanding a skill in equilibration not all of us can exert. The higher the civilization the higher the lavatory seats. These latter induce in the devotee that reposeful and contemplative frame of mind so necessary for the proper discharge of the function.

And is it really true that the maternal mortality in countries where they squat to evacuate (such as India) is practically *nil*? Because, if so, we are most grossly deceived by the practitioners of those countries. Nor can I believe that a squatting labour is entirely out of reach of puerperal sepsis. Dr. Vaughan asks: "How *can* infection arise when all the discharges flow downwards and leave the body as soon as they can be got rid of?" I do not know how, but it seems certain it can arise. It has been shown quite conclusively (King: *British Medical Journal*, March 22nd, 1930) that infection sprayed on the vulva after delivery can ascend against the tide of the lochia. Presumably a woman delivered squatting must lie down sometimes. She cannot spend the whole puerperium on her hands and knees; she would thus be as liable to that particular type of infection as a woman in any other position.—I am, etc.,

A. J. HAWES.

Erythromelalgia

SIR,—In your issue of November 5th, 1932, I wrote:

"I desire for purposes of investigation a few patients displaying severe burning pain in the feet, accompanied by redness of the skin and aggravated by warmth and the dependent position; and should be grateful for the name and address of any such patient who would be willing to attend my out-patient department at University College Hospital."

In response four patients have been referred here; these were suffering from cervical rib, erythrocyanosis, osteo-arthritis of the great toe, and severe chilblain respectively. I am grateful and have been interested in the cases, but they have not formed a series sufficient for my purpose, and I now write craving further assistance from your readers.—I am, etc.,

THOMAS LEWIS.

Department of Clinical Research, University College Hospital Medical School, W.C.1, Jan. 7th.

Miss Lawrence

SIR,—I hope you will allow me to add a few remarks to your kindly and very well deserved paragraph on my old colleague, Miss Lawrence. It is not only a pleasure but a duty to one who owed so much to her loyal help and comradeship at the British Medical Association as I did, to pay a tribute to her work and to add my best wishes for her success in her future sphere, which I feel sure will fit her like a glove—if spheres can do such a thing.

The members of our committees and the people coming into close contact with the Medical Department are fully aware of the important part she has played in the development of the Association during the last thirteen years, but to large numbers of our members she is little known. Her tremendous capacity for work was shown by the way in which she devoted literally every moment of her time to the Central Medical War Committee. Looking back at that period I cannot think how we should have managed without her. It was a real catch for the Association that we were able to keep her after the war was over, for she brought to bear on our work not only a very well trained mind and a conscientiousness which is quite abnormal, but an appreciation of medical idiosyncrasies which was remarkable and has been very useful.

Nobody ever had a more loyal colleague than she was to me, and proud as I am of her promotion (for it is a distinct score that, after being so long out of the profession for which she was trained, she should be chosen for such an important position) I am very glad that her departure from the Association did not happen in my term of office.—I am, etc.,

ALFRED COX.

London, W., Jan. 9th.

Royal Medical Benevolent Fund

SIR,—I am sure it will be of interest to your readers to know that the response to Sir Thomas Barlow's Christmas appeal amounted to £618. This sum is larger than any received in former years, and enabled gifts of thirty shillings to be distributed to 203 annuitants and thirty shillings to 209 grantees. Every penny subscribed has been distributed.

The appeal was very greatly helped by the collections made at many medical meetings, in addition to the ready and generous personal donations received. Very many grateful letters expressing thanks to the donors are being received from the recipients.—I am, etc.,

E. C. PENNEFATHER, Secretary.

London, W.1, Jan. 9th.

Obituary

CECIL F. BEADLES, F.R.C.S.

Pathological Curator, Royal College of Surgeons

By the death of Mr. Cecil Fowler Beadles the Royal College of Surgeons of England has lost a pathological curator who will always be remembered, with Paget and Shattock, as having left a very distinct and permanent mark on the Hunterian Museum—Paget by the original printed catalogue, Shattock by the revision of the latter and the rearrangement of the collection in accordance with the principles inculcated by Hunter, and Beadles by the war collection. The enormous mass of pathological material accumulated during the war, and deposited at the College of Surgeons as the central depot for its reception, was entrusted to Mr. Beadles to be dealt with in the manner he considered best. This work, achieved with untiring energy and with the exercise of the discretion required in such an undertaking, he brought to a successful issue in what now constitutes a separate section of the museum. It forms, in fact, a museum in itself of some three thousand specimens, which illustrate fully the injuries and diseases incident to warfare. Although Beadles was not curator at the time, this great collection will always, and rightly, be regarded as his creation and associated with his name. He first took up work at the museum in 1909, so that his connexion with the College was of long standing. At that time he was engaged in assisting Professor Shattock in the lengthy undertaking of the revision of the pathological catalogue and the rearrangement of the specimens, an occupation in which he was as deeply interested as in the war work. This task remained unfinished at the time of Shattock's death, when Beadles succeeded to the curatorship (1925), and shortly afterwards received the well-deserved honour of the Fellowship of the College. It was a wish very near his heart to see this revision completed, and at times, as his health declined, he sometimes seemed to doubt whether it would ever be realized. Happily, however, he had this satisfaction, and during his final illness he turned his thoughts towards the possibility of the catalogue being gradually put into printed form.

CECIL BEADLES IN 1892

There is no doubt that Beadles was an ideal curator: his whole soul was in the work. He would spare no trouble to obtain specimens to render the collections more complete. He watched the journals for accounts of interesting specimens, and would write asking the owners to present them to the museum; he took infinite care in the dissection and display of specimens; and he was assiduous in endeavouring to obtain that most important adjunct to specimens—their clinical histories. The museum was his hobby. He had no other, unless it were his garden, which he valued largely on account of the seclusion it afforded from the outside world, for he lived the life almost of a recluse. His intense application to work, coupled with the absence of proper holidays and recreation, was probably detrimental, and there is reason to think that the constant exposure to the vapour of formalin during his work on the war collection laid the seeds of the bronchial and pulmonary trouble with which he was afflicted with increasing severity in the last few years of his life. Concentration became difficult; the even tenor of his work was marred by attacks of hypertension, aggravating the inveterate insomnia from which he suffered, and for which he declined all medicinal treatment. Yet, notwithstanding these grave disabilities, he stolidly refused to slacken the work to which he was devoted, and even on his death-bed continued to give orders relating to the museum.

Although Beadles will probably be remembered chiefly in connexion with the war collection, he did good work in another sphere. Before his appointment at the College of Surgeons he filled the post of senior assistant medical officer at the London County Asylum, Colney Hatch. There he had opportunities for the study of pathological anatomy, and the *Transactions* of the Pathological Society contain many papers by him which were written at that period. He became interested more especially in the vascular supply of the brain and the variations in the distribution of the cerebral arteries, and it was his intention to write a book on that subject which should include an exhaustive account of the literature. For this purpose he spent years in collecting literary material, which from its bulk he probably found unmanageable, for he never completed the work. However, his own observations formed the subject of the Hunterian Lecture which he delivered in 1907–8, and are justly valued.

Beadles received his medical education at University College and Hospital, gaining the gold medal in histology in 1885. He qualified in 1890, and subsequently spent two years as senior house-surgeon at the Cancer Hospital. He belonged to what would perhaps now be considered the old-fashioned school of pathological anatomists. He was fond of the old Pathological Society, and regretted its extinction. He always held that pathological anatomy should form the foundation of medical and surgical knowledge.

We are indebted to Sir ARTHUR KEITH for the following appreciation:

It so happened that in 1909, when the late Professor Samuel Shattock, at the request of the Council of the College, undertook to revise and recatalogue the great collection of pathological specimens in its museum, that Mr. Cecil Beadles was at a loose end. He had by then published several papers on pathological subjects, but had had no experience of museum work. Nevertheless Professor Shattock chose him as his junior colleague in what proved to be a very heavy task. Shattock planned the great collection which now illustrates the principles of pathology, but the chief executant was Mr. Beadles. The building up of the collection of general pathology—two years was the time allotted to the task—occupied Professor Shattock and Mr. Beadles for a period of thirteen years. As they began to revise the various collections of special pathology, the senior partner of the two died. Mr. Beadles, being appointed his successor, carried on. At Mr. Beadles's request the Council of the College invited Mr. T. W. P. Lawrence to collaborate with him in the task of rearranging and bringing up to date the departments which illustrate special pathology. Last year this additional task was finished—as far as a catalogue of a growing collection can be said ever to be finished. Thus Mr. Beadles, coming to assist in a temporary task in the museum, ended by devoting twenty-three years of his life to it. He proved to be a master of museum technique, having an unrivalled skill in preparing specimens so as to bring out the essential features of a disease. He gave

the whole of his energies to what was in reality a self-appointed task.

The greatest service Mr. Beadles rendered to medicine was the preparation of the Army Medical Collection, now housed in the museum of the Royal College of Surgeons. Without doubt that collection is the most complete and most extensive representation of the wounds and diseases of the great war. Every specimen was prepared, mounted, and described by him; it was he that planned the arrangement of the collection. To be sure, Mr. Beadles had the assistance of Sergeant Mogford in building up this collection—an indebtedness which he lost no opportunity of acknowledging.

In connexion with the getting together of the material out of which the Army Medical Collection was built up, I may mention an incident which throws light on Mr. Beadles's character. Through the efforts of Sir Alfred Keogh and Sir Walter Fletcher, a system of collecting specimens from war hospitals was instituted, such specimens being forwarded to the museum of the Royal College of Surgeons. Mr. Beadles took charge of the specimens, and, in order to regularize his services, the War Office offered him a temporary commission. Nothing, however, would induce him to wear a uniform: that, he held, was for men on active service. He was permitted to serve in plain clothes, and no one ever repaid the trust placed in him by greater devotion or loyalty of service. He was a morbidly sensitive man, who covered great tenderness of heart by all kinds of subterfuges—especially by abruptness in speech and manner. Mr. Beadles, like Professor Shattock and Mr. Alban Doran, continued the traditions of devoted and unselfish service established in the museum by Paget, Eve, and Targett.

ROBERT DONALDSON, M.D., F.R.C.S.ED.

Sir William Dunn Professor of Pathology, University of London, and Director of the Pathological Laboratory, Guy's Hospital

We have to record with regret the death, on January 3rd, of Professor Robert Donaldson, at his residence in Muswell Hill, London.

Born in 1877, at Dalkeith, Donaldson received his medical education in the University of Edinburgh, where he graduated M.B., Ch.B. in 1904, obtaining the diploma D.T.M. in the same year. He became F.R.C.S.Ed. in 1909, and proceeded M.D. with honours in 1918. He had previously taken the D.P.H. at the University of Sheffield in 1912. His interest in pathology was apparent early, and he held in turn the posts of demonstrator in the Universities of Bristol and Sheffield. During the war he was bacteriological specialist to the military hospitals at Reading.

Coming subsequently to London, he held the appointment of lecturer in pathology and forensic medicine at St. George's Hospital, and was also pathologist and curator of the museum. He was pathologist, and later consulting pathologist, at the Hospital of St. John and St. Elizabeth and the Princess Louise Hospital; he also held for some time the post of bacteriologist to the Royal Borough of Kensington. He was then appointed director of the pathological laboratory and honorary pathologist to Guy's Hospital, which appointments he held until his death, together with that of Sir William Dunn professor of pathology in the University of London. In 1911 Robert Donaldson received a scientific grant from the British Medical Association. He was honorary secretary of the Section of Pathology (Human and Comparative) at the annual meeting of the Association at Glasgow in 1922, vice-president of the Section of Pathology and Bacteriology at the meeting at Nottingham in 1926, and vice-president of the Section of Pathology at the Centenary Meeting in London last year. In 1923 he published a book on practical morbid histology, and was the author of an article on the bacteriology of influenza in Crookshank's textbook, *Influenza*, in the previous year. He contributed papers on pathological subjects to various medical periodicals, including the *Lancet* and the *Journal of Pathology and Bacteriology*.

JOHN JOSEPH WADDELOW, F.R.C.S.

We have to announce the death at Whittlesey, on January 3rd, of Dr. J. J. Waddelow. He was born in 1869, the only child of the late Mr. J. Waddelow, J.P. Educated at Cambridge and King's College, he qualified L.S.A. in 1890, obtained the conjoint diploma in 1891, and the F.R.C.S. in 1896. After leaving King's College he settled in practice in Whittlesey, and in 1904 was made a justice of the peace for the Isle of Ely, taking his seat on the Whittlesey bench, of which he subsequently became chairman. His generosity, open-heartedness, and kindly nature made him popular in the district both as a doctor and as a man of public affairs. He was for many years medical officer of health for the southern area of his parish, and also medical officer of the local Poor Law institution, and certifying factory surgeon. He was an honorary life member of the British Red Cross, and belonged to the Harveian Society. Dr. Waddelow had many hobbies, being, among other things, a keen photographer, a gardener, a student of literature, and an archaeologist. He took a considerable interest in local affairs. He leaves a widow and two daughters.

Dr. ROBERT STOBO died at his residence at Welburn, York, on January 1st. He was born in June, 1866, educated at the University of Glasgow and the Newcastle College of Medicine, and graduated M.B., C.M.Glas. in 1891, and M.D. with commendation in 1906; in 1904 he took the B.Hy. (with honours) and D.P.H.Durh. After conducting an extensive practice for twenty years at Sunderland, where he became medical officer of health to the rural district council, he removed to Welburn in 1916 and became medical officer of health and public vaccinator for the Bulmer District of Malton. He retired from practice about eighteen months ago.

The following well-known foreign medical men have recently died: Dr. GEORGE STOICESCO, emeritus professor of medicine at Bucarest and corresponding member of the Académie de Médecine of Paris, aged 84; Dr. EMILE VAN ERMENGEN, professor at the Ghent Faculty of Medicine, member of the Royal Academy of Medicine, and Commander of the Order of Leopold.

The Services

DEATHS IN THE SERVICES

Colonel Vincent James Crawford, D.S.O., late R.A.M.C. (ret.), died suddenly on December 15th, aged 55, at Great Bardfield, Braintree, where he had been in practice since his retirement. He was born on March 18th, 1877, the third son of the late Surgeon General Sir Thomas Crawford, K.C.B., Director-General of the Army Medical Department fifty years ago, and was educated at Guy's, taking the M.R.C.S. and L.R.C.P.Lond. in 1899. Entering the R.A.M.C. as lieutenant on July 27th, 1899, he became lieutenant-colonel in the long war promotion list of March 1st, 1915, colonel on March 26th, 1925, and retired on October 22nd, 1927. He served in the South African war in 1900–2, when he took part in operations in the Orange Free State and in Cape Colony, receiving the Queen's and King's medals, with two clasps to each; and throughout the war of 1914–18, when he was mentioned in dispatches in the *London Gazette* of February 17th, 1915, and January 1st, 1916, and received the D.S.O. In private practice at Great Bardfield his specialization in diseases of women and children during service in the R.A.M.C. proved beneficial in his own work and in that of his colleagues. He founded a branch of the British Legion in the village, and became its first president.

Universities and Colleges

UNIVERSITY OF LONDON

The following have been recognized as teachers in the subjects indicated: *University College Hospital Medical School:* Dr. K. E. Harris (medicine). *London (Royal Free Hospital) School of Medicine for Women:* Dr. Cicely Weatherall (bacteriology). *Maudsley Hospital:* As teachers of mental diseases—Dr. A. J. Lewis (psychiatry), Dr. T. Tennent (psychological medicine). *Bethlem Royal Hospital:* Dr. E. D. Macnamara (mental diseases—psychological medicine).

Regulations for the academic diploma in medical radiology have been approved and may be obtained from the Academic Registrar. The regulations relating to degrees in medicine for external students (Blue Book, September, 1932, p. 246) have been amended by the addition of the word "pharmacy" before the word "science" in Section 2 (iii).

A course of lectures on chemical structure and pharmacological action will be given in the Department of Pharmacology, University College, by Dr. H. R. Ing, on Mondays at 5 p.m., beginning on February 13th.

The following candidates have been approved at the examination indicated:

M.D.—*Branch I (Medicine):* J. V. Armstrong, Alison M. Clark, F. S. Cliff, E. T. Conybeare (University Medal), I. Davies, W. P. Greenwood, G. B. M. Heggs, H. B. Hodson, H. W. Howell, A. Mitchell, A. M. Nussbrecher, Nellie H. Reynolds, Ursula Shelley, F. H. Stevenson, H. C. Trowell, Frances J. Vinter. *Branch II (Pathology):* C. L. Oakley, C. G. Paine, C. K. Simpson, N. Sinnadurai. *Branch IV (Midwifery and Diseases of Women):* Mabel A. Baker, Kathleen M. D. Harding, Eileen S. Morris, W. C. W. Nixon (University Medal), Everell M. Shippam, H. J. D. Smythe. *Branch V (State Medicine):* A. R. Thompson.

St. Thomas's Hospital

Two lectures on iodine and the thyroid gland will be given in the Governors' Hall, St. Thomas's Hospital, by Professor Edward Mellanby of Sheffield University, on January 26th and 27th, at 5 p.m. The first lecture will deal with goitres, experimental and clinical; the second with hypo- and hyperthyroidism. Admission is free without ticket.

Medical News

At the annual meeting of the Royal Microscopical Society, to be held in B.M.A. House, Tavistock Square, W.C., on Wednesday, January 18th, at 5.30 p.m., Mr. Conrad Beck will deliver his presidential address, entitled "Microscope illumination with transmitted light."

A dinner meeting of the West London Medico-Chirurgical Society will be held at the Hotel Rembrandt, Brompton Road, S.W., to-day (Friday) at 7.30 p.m. A discussion on arthritis will be opened by Mr. Timbrell Fisher, *M.C.*, who will speak on recent work on the pathology and treatment of arthritis; Mr. Alan Todd will speak on the orthopaedic treatment.

At the meeting of the Society of Medical Officers of Health to be held at 1, Upper Montague Street, W.C.1, on Friday, January 20th, at 5 p.m., a discussion on "What do we really mean by mental deficiency?" will be opened by Dr. G. A. Auden, followed by Dr. F. C. Shrubsall.

At a meeting of the Guild of Public Pharmacists, to be held at the Pharmaceutical Society's house, 17, Bloomsbury Square, W.C., on Wednesday, January 18th, an address, entitled "De minimis," will be given by Mr. Wilfred Trotter, F.R.S., Serjeant Surgeon to H.M. the King, and senior surgeon, University College Hospital. The chair will be taken at 7.30 p.m. by Dr. C. H. Hampshire, secretary to the Pharmacopoeia Commission, and chairman, British Pharmaceutical Conference, 1933.

At a meeting of the British Institute of Philosophy, to be held at University College, Gower Street, on Tuesday, January 17th, at 8.15 p.m., Professor F. Aveling will give a lecture on "Some contemporary contributions of psychology to philosophy," with Dr. C. S. Myers, F.R.S., in the chair. Tickets on application to director of studies at University Hall, 14, Gordon Square, W.C.1.

At a meeting of the General Council of King Edward's Hospital Fund for London, held at the offices of the Fund on January 10th, with Viscount Burnham in the chair, it was reported that the President, H.R.H. the Prince of Wales, had appointed the Earl of Onslow and Lord Wakefield to be additional members of the council. A message from the President dealing with the report of Lord Onslow's committee on the out-patient question, and with the action to be taken in the future, was also read. [This report was noticed in our columns on January 7th.] Resolutions were passed providing for the work of the Fund for 1933.

The London and Home Counties Branch of the Library Association has arranged a meeting to be held at the Middlesex Hospital Nurses' Home, Foley Street, W., on Wednesday, January 25th, at 3 p.m., when those engaged in hospital library work will have an opportunity to discuss the many problems that have arisen, and will continue to arise, as this work develops. Short papers will be read by the honorary librarians of the Middlesex and Guy's Hospitals, by Dr. Kimber, medical superintendent, Herts County Mental Hospital, Mr. Bedwell, house governor of King's College Hospital, and Mr. Bolton, borough librarian, Watford. A contribution will also be made to the discussion by a representative of the London County Council Public Assistance Department. It is hoped to arrange an exhibition of methods and stationery, including book labels, etc., now employed by the hospital libraries. Illustrations showing arrangements for transporting books from ward to ward, or any other exhibit likely to prove of interest, should be sent to Mr. George R. Bolton, F.I.A., Public Library, Watford, by January 21st.

On Friday, January 20th, at 8.45 p.m., at the Princess Elizabeth of York Hospital for Children, Shadwell, Colonel W. P. MacArthur will give a lantern lecture entitled "Plague in England in old times." The medical officer of health for Stepney will take the chair. Visitors invited.

A course of lectures on some aspects and problems of medical and industrial psychology will be given at the London School of Hygiene and Tropical Medicine on Mondays and Wednesdays during the present term. The lecturers will be Professor M. Culpin, professor of medical industrial psychology in the University, Mr. Eric Farmer, Professor Major Greenwood, F.R.S., and Dr. May Smith. The first lecture—a historical introduction—will be given by Professor Greenwood on January 16th at 2 p.m. The course is primarily intended for students taking the diploma in public health or the diploma in industrial psychology of the University of London, but members of the medical profession or students of the University of London are cordially invited to attend. Special lectures in medical and industrial psychology will also be given at times to be arranged.

The programme of Friday evening discourses at the Royal Institution before Easter is of unusual interest. On January 20th Sir William Bragg will discuss the crystals of the living body; on January 27th Sir Charles Peers, the ancient monuments of England; on February 3rd Dr. Cyril Norwood, the use of the English language; on February 10th Professor A. V. Hill, the physical nature of the nerve impulse; on February 17th Professor J. D. Wilson, the plot of *Hamlet*; on February 24th Professor W. A. Bone, the photographic analysis of explosion flames; on March 3rd Lord Ashfield, London passenger transport; on March 10th Lord Rutherford, recent researches on transmutation of the elements; on March 17th Professor W. L. Bragg, the structure of alloys; on March 24th Professor G. Elliot Smith, mind and man; and on March 31st Sir Frederick Keeble, the nitrogen hunger of the world. The discourses are given at 9 p.m. at 21, Albemarle Street, W. A series of lectures on recent advances in genetics will be given on Thursdays from January 19th to February 9th, at 5.15 p.m., by Professor J. B. S. Haldane; and Professor Elliot Smith will lecture on the evolution of the mind on Thursdays, at the same hour, from March 16th to April 6th. On Saturdays, at 2 p.m., from March 18th to April 1st, films will be shown illustrating developments in cinematography.

A course on practical problems in medicine and surgery, arranged by the Fellowship of Medicine, will begin on January 17th, at 4 p.m., at 11, Chandos Street, W., with a lecture by Dr. Daniel Davies on "Views on the aetiology and treatment of peptic ulcer." There will be a demonstration of x-ray films of the chest, heart, and intestinal tract at the same place on January 20th, at 4.30. A whole-day course in cardiology will be held at the National Heart Hospital from January 16th to 27th. A demonstration on diseases of children will be given at the National Temperance Hospital at 8 p.m. on January 26th. A course in dermatology will take place at St. John's Hospital from January 30th to February 25th, and a week-end course in physical medicine at the London Clinic on February 11th and 12th. Courses, lectures, and demonstrations are open only to members and associates of the Fellowship of Medicine, 1, Wimpole Street, W.1.

On January 16th the People's League of Health will commence its twelfth annual series of the Sims Woodhead Memorial Lectures, consisting of thirteen educational health lectures, to be given at the headquarters of the National Union of Teachers, Hamilton House, Mabledon Place, W.C., on thirteen consecutive Mondays, at 6 p.m. The lecturers include Dr. W. G. Willoughby, Sir Leonard Hill, Dr. J. S. Fairbairn, Dr. P. Manson-Bahr, Sir Thomas Oliver, and Sir Frederick Hobday. Tickets for the series, and all particulars, may be obtained from the general secretary of the League, 12, Stratford Place, W.1. Price of full course ticket, 10s.; single lectures, 1s. each.

The council of the Royal Sanitary Institute (90, Buckingham Palace Road, S.W.1) has arranged for visits on Saturday, February 4th, to the new sewage works of the city of Coventry at Finham, and to the new abattoir for the city at Upper York Street, The Butts. Those proposing to take part in either or both of the visits should notify the secretary of the Institute by January 21st.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology, Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Scabies

"ACARUS" asks for advice in the treatment of the following case. The patient has been suffering from scabies for the past twelve months, and the usual textbook treatment gives but temporary relief.

Cracked Nails

Dr. ALFRED ILES (Taunton) writes, in reply to Dr. Pollard: "Durofix," obtainable for 6d. from any ironmonger, is certain in its relief from discomfort, and, if not complicated by infection or disease, obtains a speedy cure. It is much used by radiologists, whose hands are notoriously tender, and can therefore be taken to be quite safe to use on the nail or skin.

Income Tax

Sale of Practice—Cash Basis

"C. S." has been assessed on the cash basis. As from January 1st he is taking "X" into partnership on an equal share basis, and "X" will take over the whole practice as from July 1st. It is intended to treat the practice as a new one as from January 1st, and the inspector of taxes has been notified accordingly. He has asked to see the partnership agreement, and has inquired what "C. S." proposes to do as regards receipts from accounts outstanding at January 1st.

** The partnership agreement should be forwarded to the inspector of taxes for his perusal—the request is reasonable in the circumstances. "C. S." might inform the inspector that he is advised that as there is no reason to suppose that the assessments for the past six years on the cash basis have been less than they would on a "bookings" basis he has accounted for his full liability, and the receipts after December 31st merely represent the collection of income on which tax has in effect already been assessed.

LETTERS, NOTES, ETC.

Epsom College

"A GRATEFUL PATIENT" writes: Having read Dr. Raymond Crawfurd's appeal in your issue of December 31st, 1932 (p. 1208), I have sent him one guinea in the hope that 499 other grateful patients will do the same—as they should.

"A Cure for Insomnia"

"C. H. A." writes: I suggested to an elderly man who, owing to business worries, was waking at 5 a.m. and lying sleepless till getting-up time, that he should rise from his bed and wander round the house till he was thoroughly chilled. Then he should return to his warm bed. He was inclined to try this scheme when I told him I had read of it in Boswell's *Life of Johnson*, of which book he was an admirer. The success, he told me later, was great, and in his opinion was due to the delicious sensation of the warm bed diverting the mind from business anxieties, and so sleep came.

Frost Precautions for Motorists

The following advice for preventing damage to motor cars during periods of frost is given by the Automobile Association: (1) When a car is out of use drain the radiator, cylinder jackets, and pump casing. It is not enough on many cars merely to open the radiator drain tap. (2) For cars in use either of the following safeguards should be employed: In the absence of an adequate heating system for the whole garage, a special lamp or other heating apparatus of sufficient power should be placed under the bonnet. The latter and the radiator should be completely covered with rugs. Thermal wastage can also be minimized under running conditions if a muff is used. Introduce into the water-circulating system one of the various compounds available for lowering the freezing point. Experiments to check the results obtained with, and the best proportions of, such compounds have been carried out by the technical staff, and full information on this subject can be obtained from the A.A. headquarters, Fanum House, New Coventry Street, W.1.

New Year Chocolates

We have received from Cadbury Bros. Ltd. a selection of their goods representative of the art of fine chocolate making at Bournville, the largest cocoa and chocolate factory in the world. Cadbury's have had remarkable success in recent months with their "Bourn-Vita" food-drink. This is made with fresh full-cream milk and eggs from British farms, British malt, and Empire cocoa.

In our recent review of *What is Sex?* by Dr. Helena Wright, it should have been stated that Mr. G. C. Turner, who writes an introduction to the book, is headmaster of Marlborough College.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 42, 43, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 11.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

20 Carbon Tetrachloride Poisoning

K. O. MÖLLER (*Ugeskrift for Laeger*, September 15th, 1932, p. 897), who is attached to the University Pharmacological Institute in Copenhagen, draws attention to the popularity carbon tetrachloride enjoys as a preparation for the dry-cleaning of clothes. From one to three litres are sold at a time, the public buying it of chemists under the popular name of "tetra." It is used extensively as a fire extinguisher, notably in electric works. Being 5.3 times heavier than air, it puts out a fire by displacing oxygen in the lowest level of a room. In hairdressing, carbon tetrachloride possesses many advantages. It dissolves fat, making hair look clean and glossy; it does not interfere with curls and permanent waves; and its use does not entail the loss of time incurred in the process of drying after the hair has been washed with soap and water. The use of carbon tetrachloride in hairdressing is reprehensible on account of the risks of serious poisoning, and the author has no doubt that a systematic investigation would reveal a long series of cases similar to the four he records in detail. None of them was fatal. The first two were hairdressing cases; the last two occurred in connexion with the dry-cleaning of clothing. While the use of carbon tetrachloride in hairdressing is indefensible, its merits in the dry-cleaning of clothing must be weighed against those of petrol. Möller remarks that the latter is responsible for so many explosions and burns that if preference is to be given to one or other of these chemicals it should be awarded to carbon tetrachloride, provided that the public is educated as to its dangers. The bottles in which it is sold should be provided with a plain statement about its dangerous properties, and the risks of using it in a closed and badly ventilated room.

21 Diagnosis of *Stenosis of the Inferior Vena Cava*

G. KATZ (*Münch. med. Woch.*, October 14th, 1932, p. 1676) points out that venous stasis is usually confined to the lower limbs and trunk. When there is oedema of the lower limbs, anasarca, and ascites, it is sometimes difficult to diagnose between failure of the right side of the heart and stenosis of the inferior vena cava due to thrombosis or pressure from without by a tumour. A collateral circulation between the inferior epigastric and the internal mammary veins may be established even when there is a certain amount of blood passing through the inferior vena cava; alternatively, when there is complete stenosis of the vena cava, the collateral circulation may not be demonstrable owing to the anasarca. In such stenosis the blood reaches the superior vena cava from the subcutaneous abdominal and internal mammary veins, partly from the femoral through the superficial epigastric vein, and partly from the iliac through the inferior epigastric. This collateral route is longer than that of the inferior vena cava, and the blood has to pass along narrower channels, two factors which retard the circulation. Katz states that a manifest retardation of the circulation from the lower extremities is positive proof of stenosis of the inferior vena cava. To demonstrate this, 1 c.cm. of a 50 per cent. solution of a bromine and calcium preparation is injected into the cubital vein of the patient. The calcium ions stimulate the warmth-sensitive nerve endings of the skin and mucous membranes in the head. The time taken for this feeling of warmth to appear after injection is noted, and in a healthy patient is usually about ten seconds. The author states that the length of the circulation from the cubital vein to the arterial twigs of the carotid is about 170 cm. The rate of flow is therefore about 13 cm. per second. A similar injection is made into the small saphenous vein. Since the route of the circulation from this point is approximately 65 cm. longer, about twenty seconds elapse before a feeling of warmth is experienced in the head. Normally, there is a difference of seven to ten seconds in the rate of flow; when the inferior vena cava is stenosed the difference may be as much as fifty-five seconds, due to the longer route traversed by the collateral circulation and the narrowness of the channels. Katz considers this procedure a simple, harmless method of obtaining a differential diagnosis of venous stasis due to cardiac or caval origin.

22 Cutaneous Gangrene in Scarlet Fever

H. D. PASACHOFF and N. SOBEL (*Arch. Derm. and Syph.*, September, 1932, p. 428) record a case of disseminated gangrene of the skin occurring in a previously healthy boy aged 5 years in the third week of a moderately severe attack of scarlet fever, and concurrently with severe pharyngitis, cervical adenitis, and albuminuria. A generalized pustular eruption appeared on the twenty-first day, and a number of the lesions passed into gangrene and ulceration. The blood culture was sterile, but *Staphylococcus aureus* was recovered from a gangrenous area. Complete recovery took place in about three months with superficial and deep scarring.

Surgery

23 Diverticula and Tumours of the Pericardium

R. KIENBÖCK and K. WEISS (*Wien. Arch. f. innere Med.*, October 1st, 1932, p. 155) state that in the *x*-ray diagnosis of the intrathoracic tumours not enough care is taken to ascertain their exact site and whether they are benign or malignant. Pericardial diverticula and tumours should be borne in mind in the diagnosis of mediastinal tumours. The former are usually pulsion diverticula occurring in old cases of adhesive pericarditis. Primary malignant tumours of the pericardium appear as lymphogranulomata, lymphosarcomata, and giant-cell sarcomata. Secondary tumours may come from the mediastinum, lung, or distant parts by way of the lymphatics or veins. The symptoms of these conditions are not characteristic; they are of long duration, and may occur at any age. The patient complains of dyspnoea and cough, of stabbing pain in the chest, and of a feeling of pressure in the chest with lassitude, anxiety, and nervousness. Later, in malignant cases, there is loss of weight, anaemia, haemoptysis, and pyrexia. In the case of diverticula, the general condition of the patient is good. On examination the patient is seen to be dyspnoeic; the heart dullness is increased usually to the right; there may be an abnormal area of dullness on the back; the apex beat is lost; the heart sounds are normal or unusually soft; there is no abnormal pulsation in the chest; and tapping gives a fluid which is slightly blood-stained or normal. On *x*-ray examination the heart-shadow is increased in size in its lower half, while the infraclavicular part is unaffected. A localized prominence is seen, which may be smooth and convex or irregular; it varies in size from an egg to a foetal head. There is usually a greater increase in the transverse than in the vertical diameter. The prominence is usually on the right side of the heart, sometimes on the left, and uncommonly on both sides. The lungs are normal, but occasionally a pleural exudate can be seen. On inspiration a light "lung gusset" is seen at the lower lateral convexity of the prominence, and the contour of the inferior vena cava may be made out. In the differential diagnosis the various inflammatory affections and new growths of the heart, pericardium, lungs, pleura, and mediastinum have to be considered. In the

x-ray diagnosis of a large intrathoracic mass in the neighbourhood of the heart the following have to be borne in mind: benign tumours of the pericardium—neurofibromata, chondromata, and dermoid cysts; inflammatory pericardial diverticula; aneurysms of the aorta and pulmonary artery; and great dilatation of the auricles. The treatment of pericardial diverticula is that of chronic pericarditis; the condition is rarely amenable to operation. Malignant tumours should be exposed to *x* rays and general treatment be instituted. Operative treatment is dangerous and ineffective. It may be indicated, however, in circumscribed tumours which have not metastatized, occurring in patients with sound hearts.

24 Prostatic Resection

T. M. DAVIS (*Minnesota Med.*, October, 1932, p. 666) believes that in many cases of prostatitis resection is a sufficiently adequate measure, and that recurrences will be few. Since the prostate diminishes in size with the removal of residual urine through a cystotomy opening, the same shrinkage follows the adequate drainage consequent on the removal of tissue impinging on the vesical orifice and posterior urethra. When this can be secured by transurethral resection, prostatectomy becomes unnecessary. Thorough decompression with a retained urethral catheter is of paramount pre-operative importance. Resection is performed by suitable electric charges applied through special instruments within the urethra; the Sterns resectoscope and the McCarthy electrotome are considered excellent appliances. The control of haemorrhage is the chief difficulty in transurethral operations, but with suitable currents haemostasis can be rapidly and permanently attained. Excessive coagulation must be avoided in order to prevent sloughing and secondary haemorrhages. The amount of tissue to be removed varies with the type and amount of obstruction; when this is large at least two-thirds of the obstructing gland must be removed. Davis describes the various electric instruments and currents, and analyses the results in 374 cases. H. C. BUMPUS, jun. (ibid., p. 671), also advocates this method of treating enlargements of the prostate, and briefly records the results in 186 cases. In these an instrument designed by Braasch was employed, and the technique is described. He believes, however, that only 5 to 10 grams of tissue should usually be removed, and that excision of the greater part of the gland is contraindicated.

25 Peritoneal Drainage in Appendix Operations

G. H. COLT and MARGARET M. M. MORRISON (*Brit. Journ. Surg.*, October, 1932, p. 197) state that a statistical analysis of 1,408 cases of acute appendicitis occurring between 1911 and 1929 has failed to justify any conclusion for or against drainage of the peritoneal cavity in appendix operations. While the material for the report was being arranged, it became evident that in general the worse the case the more frequently was drainage employed; only a small proportion of "acute with lymph" cases were drained as compared with the gangrenous perforated type. The authors are convinced that the old surgical rule of employing a short and simple route to the focus of infection is to be commended; during the years 1911 to 1923 in their series of 632 cases the mortality with the McBurney incision was greater than that with the Battle incision in nearly all stages of the disease. Only a small number of cases of the paracentral incision were available for comparison, but in these the mortality was also higher than that in the Battle series, because there is a distinct risk of spreading infection owing to the packing off of bacteria. A drain is therefore used by most surgeons in doubtful cases, and the risk of introducing infection thereby is very small. The Battle incision is emphasized by the authors as being definitely preferable, except when there is doubt as to the nature of the case—notably in women, or when the appendix is median and pelvic in position. With a median appendix localization the short subumbilical paracentral incision should prove safer than that of Battle.

Therapeutics

26 Evaporated Milk in Food Allergy and Infant Feeding

J. B. ROSS (*Med. Journ. and Record*, October 5th, 1932, p. 276) states that evaporated milk is growing in favour as a substitute for human milk and as a therapeutical agent. Pure cow's milk is evaporated *in vacuo* until approximately 60 per cent. of water has been removed; the fat globules are broken up and distributed evenly throughout the milk. Afterwards the milk is hermetically sealed in tins and sterilized, thereby destroying any accidental bacterial contamination. The curds formed in an infant's stomach are soft, small, and flocculent, resembling those of breast milk. Evaporated milk contains the normal quantity of vitamins A and B, but the heating destroys vitamin C. The latter, however, is present in so small a quantity in fresh cow's or even human milk that orange or tomato juice is introduced usually into the diet. Fresh milk contains but little of vitamin D, and cod-liver oil is thus required. The iron content of cow's milk, and therefore of evaporated milk (when diluted for infant feeding), is deficient; egg yolk is therefore added to the diluted milk in order to provide iron. Evaporated milk is used frequently for acidulated feedings—lemon juice or lactic acid is added in order to neutralize the buffer substance present in cow's milk. Lemon juice is sufficiently acid for this purpose, and also contains the necessary antiscorbutic vitamin C. Ross has found an evaporated milk formula remarkably successful in the treatment of children suffering from food allergy, such as dyspepsia, bronchitis, and nervous symptoms. Many cases of infantile eczema are relieved by the use of evaporated milk: apparently the sterilization and heating diminish the liability to excite protein-sensitivity symptoms.

27 Treatment of Chorea Minor with Luminal

P. DRUCKER (*Hospitalstidende*, September 1st, 1932, p. 1066) reports from the Children's Department of the Rigshospital in Copenhagen trials, begun in 1928, with luminal in the treatment of chorea minor. The first six children to be thus treated were given 10 to 15 cg. daily; a certain beneficial effect on the twitchings resulted, but it was by no means so great that a definite therapeutic advance could be claimed. It was not till the initial daily dosage had been increased to 30 cg. a day that the action of this drug on the course and duration of the disease was seen to be so striking that, after January, 1930, luminal was adopted as the only drug used in uncomplicated chorea minor. In the period from January, 1930, to March, 1931, fifteen children between the ages of 8 and 13 were thus treated. The initial dosage was 10 cg., given three times a day. This was continued for a fortnight, or until a rash appeared, a complication usually occurring about ten days after the beginning of the treatment, when the luminal was discontinued until the rash had completely or almost completely disappeared. The treatment was then resumed for a month with 5 cg. three times a day, and for another month with 5 cg. twice a day. This treatment was thus continued for two and a half months, during which it was supplemented by the customary isolation and rest in bed. For the first six weeks the children were spoon-fed, and they were given massage of the lower limbs before they were allowed to get up. In uncomplicated cases the duration of this treatment might be considerably shortened, for the symptoms disappear long before its completion. But the wisdom of the policy of letting the children get up and return home after three or four weeks because they were symptom-free is considered doubtful, for the risk of relapse is undoubtedly enhanced. After only a few days from the beginning of treatment the children became quieter, and after about a week they were as a rule very drowsy, twelve of the fifteen developing incontinence of both urine and faeces. The rash, which occurred in about a

third of all the cases, and which was associated with a rise of the temperature, did not seem to diminish the benefits of the treatment. The relapses, observed only in three of the fifteen cases, were all mild. Drucker adds that in view of the careful nursing this treatment entails, it is well not to attempt it in the child's home.

Radiology

28 Urography in Renal Tuberculosis

E. SIMON (*Zeit. f. Urol.*, 1932, Band 26, Heft 9, p. 41) deplores that *x*-ray examination of the kidneys is not more used in the diagnosis of tuberculosis. He states that the fear of carrying bacilli to the healthy kidney by catheterization has proved to be groundless in the experience of the last twenty years. There are several typical features of renal tuberculosis as shown by the pyelogram. They are: broadening at the base of one calyx; changes in the renal pelvis, which may be dilated or contracted; signs of small cavities near the periphery, which appear to have no connexion with the pelvis; the absence of one or more calyces resulting from fibrous contraction or because they were filled up with caseous material. When the kidney is destroyed by the inflammatory process, the differences between a tuberculous and an ordinary pyonephrotic kidney are no longer clear. Although the author does not disparage the merits of retrograde urography, he draws attention to the fact that excretion urography is the method of choice in diagnosis, supplemented by the former and by cystoscopic examination. In the earliest cases excretion urography gives as good results as the retrograde method. In later cases, if there is a negative excretion pyelogram, it diagnoses the diseased kidney and gives an indication for further examination, and perhaps in clear cases for nephrectomy. In the latest cases when there is great contraction of the bladder, and cystoscopy and retrograde catheterization are impossible, a negative excretion pyelogram will show the side on which the diseased kidney lies, to what extent it has lost its function, and to what extent the other kidney is involved. Thus it is unnecessary to perform an exploratory nephrotomy.

29 Radiography of the Pulmonary Circulation

Recent advances in radiography have rendered visible the cerebral arteries and the larger abdominal vessels following the injection of an opaque substance into the aorta. L. DE CARVALHO, E. MONTIZ, and A. SALDANHA (*Journ. de Radiol. et d'Electrol.*, October, 1932, p. 469) find that this method is useless in the case of the pulmonary circulation, since it is very difficult to inject an opaque fluid into the pulmonary artery, while an injection into a superficial vein becomes so dilute as to be invisible. Further, the great vascularity of the lung tissue renders it difficult to obtain a well-defined arterial image. It is necessary, therefore, that the opaque fluid should be introduced into the superior vena cava, or, preferably, into the right auricle. After many experiments the authors devised the following method. The patient, while fasting, and seated, raises his right arm slightly; a special catheter, opaque to *x* rays, is lubricated with a 10 per cent. sodium citrate solution, and is introduced into the median basilic vein by means of a small trocar and cannula, or by an incision when the vein is thin-walled. The catheter is pushed slowly under radioscopic control into the lower extremity of the superior vena cava or even into the right auricle. Physiological saline solution is injected slowly through the catheter to facilitate its introduction. With the patient's arm still slightly raised, the sound can be guided by the fingers past the entrance of the external jugular into the subclavian vein. On reaching the superior vena cava or the auricle, a quantity (2.5 to 2.75 drachms) of a 12 per cent. sodium iodide solution is injected until the opaque blood reaches the pulmonary arterioles. If the injection is carried into the capillaries the whole lung becomes opaque and no details can be seen. When the skiagram is complete, the sound is washed out with sodium citrate solution and withdrawn. Patients may complain of cough, a metallic taste, transient headache, and coryza. Plates of six cases taken before and after injection show that such pulmonary radiography reveals details otherwise invisible.

30 Ultra-violet Radiation of the Interior of the Bladder

H. MESCHEDE (*Wien. klin. Woch.*, October 28th, 1932, p. 1350) describes some cases of bladder disease which he has alleviated by exposing the interior of the bladder to ultra-violet rays. It was first tried in tuberculosis of the bladder. A quartz tube, 26 cm. in length and 7 mm. in diameter, is introduced into the bladder like a cystoscope, and the free end is attached to a quartz lamp. (In a later modification of the instrument the author has made the free end ten times as large as that which is in the bladder: this enables him to view the interior of the bladder and focus the rays on the affected parts.) Meschede states that the interior of the bladder is ten times as resistant to ultra-violet rays as the skin; an erythema of the skin is produced at a distance of 3 cm. in three minutes, whereas in the bladder it requires half an hour. After ultra-violet radiation the bladder irritability is increased and the patient micturates less frequently. The patient thus gains confidence in this form of treatment, which is at first somewhat painful. There is a rapid increase of the bladder capacity. The erythema produced is a sign of the reaction on the part of the bladder tissue needed in the healing of chronic inflammatory processes. The whole of the interior of the bladder is irradiated, with special attention to the affected areas. Even in acute cystitis ultra-violet radiation may be used owing to the high bactericidal action of the rays. The one disadvantage of this form of treatment is that it takes up much time; the bladder is irradiated two or three times a week. The author has used ultra-violet rays for six months, and believes that they promise hope in a large number of cases. In several incurable cases the author was able to make life bearable for the patients.

Obstetrics and Gynaecology

31 Brain Haemorrhages in Eclampsia

H. RHEINDORF (*Zentralbl. f. Gynäk.*, October 1st, 1932, p. 2413) describes two cases of eclampsia terminating fatally with large haemorrhages into the brain. In the first the subarachnoid space and all the ventricles were filled with fluid blood. The brain was moist but not swollen. In the pons and the subjacent left part of the cerebellum there was a haemorrhage the size of a hen's egg, which had destroyed the ependyma and burst into the fourth ventricle. There were a few other small haemorrhages in the cerebrum. In the second case the gyri on the surface of the brain were broader than normal and swollen; the sulci were less deep than normal. On horizontal section the ganglia on the left side were found to be destroyed, and a large blood clot was discovered in the left lateral ventricle. The right lateral ventricle was filled with dark red fluid blood. No blood was present in the fourth ventricle. The author remarks that large haemorrhages into the brain occur in 10 per cent. of fatal cases. They vary from the size of a pin-head to that of an egg, and occur chiefly in the brain substance, pons, and central ganglia; larger haemorrhages which burst into the ventricles are uncommon. Some authors believe that these haemorrhages are due to thrombosis which damages the wall of the blood vessels, which give way when the blood pressure is unduly raised. Others think that the rise in blood pressure alone is sufficient to account for a giving way of the blood vessels. A number of dissecting aneurysms have been found in some cases, the rupture of one having caused haemorrhage. A change in the arteries and veins of pregnant women has been described in which foci of new muscular tissue have been

found in the middle coat. This new tissue is easily destroyed, and undergoes fatty degeneration at the end of pregnancy. Rheindorf was unable to find evidence of any such change. He believes that haemorrhage into the brain is due to damaged blood vessels, which, in a condition in which the blood pressure is already raised and which is still further raised with the onset of convulsions, are easily liable to rupture.

32 Rupture of the Uterus

S. KOBRINSKY (*Canadian Med. Assoc. Journ.*, October, 1932, p. 385) reports a case of uterine rupture during labour, and draws certain conclusions based on it in conjunction with a study of the literature. The possibility of such an accident must always be kept in mind in normal labour, for it may occur completely without signs of shock or severe haemorrhage. In his own case there was only a tearing feeling and a burning sensation in the left lower quadrant, followed by severe pain but no vaginal haemorrhage. No pituitary extract had been given, but Kobrinsky repeats the warning that too much indiscriminate use of this drug is going on. Laparotomy rendered the diagnosis obvious, and a subtotal hysterectomy was performed with drainage; this is considered by the author to be the treatment promising the best results. Convalescence was speedy and satisfactory. He estimates that the incidence in Canada of this condition in 1930 was about 1 in 8,700 cases. Hospital figures are higher than this because the incidence of abnormal pregnancies treated in these institutions is higher than in the general population. Cases occurring during labour usually show no premonitory signs. A sudden tearing sensation is followed by a persistent sharp pain, localized more or less in the vicinity of the rupture. The uterine contractions cease, especially if the whole or part of the foetus has been expelled into the abdominal cavity. Conservative treatment such as packing is inadvisable. The maternal mortality rate rises rapidly with every hour which is allowed to elapse between the rupture and the operation. In Kobrinsky's case the anaesthetics used were ethylene and ether. The uterus was found to be perfectly normal histologically, apart from the tear.

Pathology

33 Calcinosis with Arterial Degeneration

The clinical and pathological observations in a case of calcinosis with widespread arterial degeneration which proved fatal at the age of 2¼ years are reported by R. LIGHTWOOD (*Arch. Dis. in Child.*, August, 1932, p. 193), who remarks that evidence is accumulating in favour of the view that there are conditions in childhood, other than that of hypervitaminosis D, which can give rise to pathological calcification, and that some of these cases are associated with extreme arterial degeneration. In his patient, a dwarfed female child, the skin was yellow, the urine albuminous, the blood pressure high, and the peripheral arteries hard and tortuous. Radiography revealed the presence of irregular transverse bands of osteosclerosis and osteoporosis in the metaphyses of certain of the long bones, associated with excessive calcification of the skull and calcification of the larger peripheral arteries. The combination of retarded growth with renal disease suggested a diagnosis of renal dwarfism, but in this condition extreme arterial disease and calcinosis are exceedingly rare. Lightwood considers that the question must be left open whether the renal or the arterial disease was primary, but abnormal tissue calcification was evident. The possible aetiological precursors of this are discussed, but there was no definite evidence obtainable of dietetic errors as regards calcium and phosphorus, or of a parathyroid activity. Lime-water had been administered since the age of 8 months, but this is not considered as being more than a possible contributory factor. The association of a rachitic state in the growing cartilage with an excess of calcium in the tissues and a somewhat high phosphorus value in the blood, together with the alternating zones of osteoporosis and osteosclerosis in the tibia, is believed by the author to indicate some phasic disorder of calcium and phosphorus metabolism in this case, and to demand extra caution in interpreting the calcium and phosphorus values. The aetiology of the arterial disease could not be determined, nor was its relation to the disordered calcium and phosphorus metabolism fully understood. An extreme obliterative endarteritis may have predisposed to local tissue degenerations; and a slightly excessive intake of lime, in the virtual absence of bone growth, may have been a factor in the deposition of calcium in the damaged arteries, degenerating tissues, and in the bones. The calcinosis was certainly not due to any excessive intake of vitamin D.

34 Experimental Scarlet Fever

K. H. HOFFKEN (*Jahrb. f. Kinderheilk.*, September, 1932, p. 351) gives in tabular form a record of previous attempts to inoculate animals with scarlet fever, and reports his own experiments. Four guinea-pigs were each injected intraperitoneally with 4 c.cm. of blood taken from patients on the first or second day of the eruption. None of the animals developed symptoms of scarlet fever, though two showed an eosinophilia of 2 and 6 per cent. respectively. Six rabbits were inoculated as follows: three intravenous and intraperitoneal injections of 2 c.cm. of blood from patients on the first or second day of the eruption were given with an interval of two days between the injections, but none of the typical symptoms of scarlet fever developed. The extinction sign, however, could be produced in human patients by injection of serum obtained by cardiac puncture of the rabbits on the twelfth and the eighteenth day after the first injection. No blanching, on the other hand, followed the injection of (1) normal rabbit serum, (2) the serum of rabbits treated with normal human blood, or (3) the serum of animals injected with the blood of persons with high fever (*pneumonia, influenza*).

35 Subclinical Infection with Brucella

P. DOOLEY (*Arch. Int. Med.*, September, 1932, p. 373) records observations made in a boarding school for boys in Connecticut on infection with *Br. abortus*. Previous to November 27th, 1930, the serums of a number of boys who had been tested gave uniformly negative agglutination reactions. On this date a boy developed undulant fever, and a second case occurred on December 27th; in both instances *Br. abortus* was isolated from the blood and stools. The school was supplied with certified grade A milk from the herd of about a hundred Holstein cows. Investigation revealed the fact that one cow had miscarried on November 13th, her milk being used for the first time on November 18th. This milk was shown to contain *Br. abortus*. Four other cows in the herd gave a positive agglutination reaction, though their milk did not appear to be infected. These five cows were removed from the herd, pasteurization of the milk was commenced, and no raw milk was consumed after December 20th. A study of the serums from 232 boys and 31 young adults in the school was commenced, the tests being continued apparently over a period of about six months. Of these serums 155 proved completely negative, while 109 agglutinated *Br. abortus* to a titre of 1 in 10 or over. No fewer than forty-seven serums reacted at 1 in 80 or over, while nine serums, including those from the two undulant fever cases, reacted at 1 in 1,280 or over. Examining the records of the fifteen persons whose serum agglutinated at 1 in 320 or over, it was found that two had clinical undulant fever, five had febrile illnesses the exact causation of which was doubtful, and eight had no illness whatever. The author regards the appearance of agglutinins as a specific response to milk-borne infection, and draws attention to the fact that these may appear in the serum without any clinical evidence of disease. In such cases diagnosis of *abortus* infection on serological grounds alone is apt to be misleading.

BISEDIA

A combination of Schacht's pure Bismuth and Pepsina Liquida with Sedatives ..

Gives excellent results in the treatment of Acute Dyspepsia, Gastric Ulceration, Vomiting of Pregnancy and Gastric Hyperasthenia.

"Please send me 16 oz. bottle of BISEDIA.
I always like to have a bottle here for emergencies.
I have used it personally and on patients by prescription for many years and it has never failed me where indicated."

INSULIN (BOOTS)

IS prepared in the Laboratories of Boots Pure Drug Company Ltd., under Licence No. 19 (Therapeutic Substances Act, 1925) of the Ministry of Health. It is made from selected ox pancreas which is subject to the strictest examination before use. The company possesses specially equipped Analytical, Pharmacological and Bacteriological Laboratories in which all the tests required by the Therapeutic Substances Act are carried out. Each batch of Insulin (Boots) is tested for potency against the International Standard Insulin and also for sterility—these tests being carried out both before and after filling into ampoules. Samples of each batch, together with reports on the potency and bacteriological tests made, are submitted to the British Medical Research Council whose certificate of correct strength and of sterility is obtained before the batch is issued.

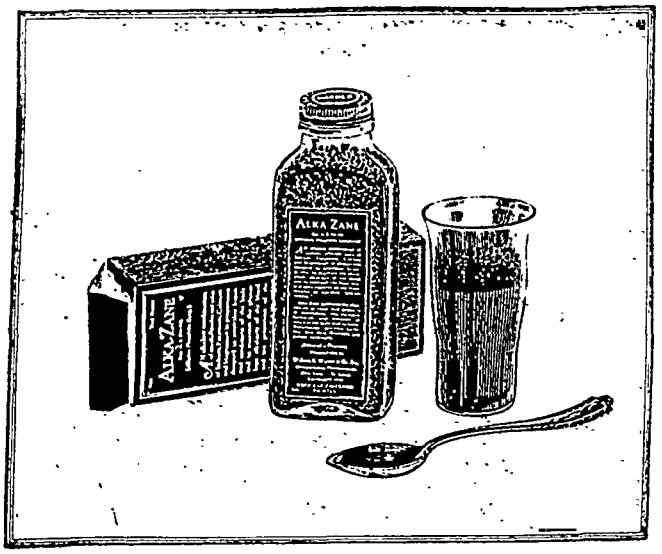
Rational Alkaline Medication



A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

must be adapted to the physiological requirements of the human organism, in order to neutralize excess acid products and restore alkaline balance, without the risk of intoxication.
A trial will promptly convince you of the value of Alka-Zane as antacid, diuretic, and to restore normal alkalinity, in gouty and rheumatic conditions, gastric or intestinal hyperacidity, and in certain skin diseases.

The many therapeutic uses of

MARMITE

(Registered Trade Mark)

have now been summarised in a small booklet, entitled

"The Medicinal and Dietetic Value of Marmite."

The information contained in this booklet has been compiled from the findings of recent scientific and clinical research, and is presented in a concise form which should appeal to the busy physician. Evidence is cited which proves the value of Marmite—the well-known yeast extract—in the prophylaxis and treatment of diseases associated with Vitamin B deficiency.

Reference is made to the special efficacy of Marmite in various types of anæmia, and to the suggestion that Marmite therapy may even replace that of liver in combating Addisonian pernicious anæmia.

If you have not already received a copy of this interesting booklet you are invited to apply to

FIRM, COMFORTABLE SUPPORTS
FOR SUB-LUXATION *of*
SACRO-ILIAC JOINT

CORSETS SALTAIR SURGICAL SERVICE AND BELTS

Above is a new type of Short Corset that has been produced to meet the demands of Modern Fashions. Lace top and low back.

Firm, consistent support, with a correct grip on the pelvis, are essential features of SALT'S SACRO-ILIAC CORSETS AND BELTS. Yet at all times these supports are truly comfortable, enabling wearers to go about their avocations and recreations in complete freedom and safety. They are a PROVED support for sub-luxation of the Sacro-iliac Joint . . . designed to the instructions of a leading Orthopaedic Specialist. They are, of course, supplied under the terms of SALT'S Guarantee, and illustrated details with simple order forms will be sent to any Medical Man interested.

London Consulting Rooms:
"OAKLEY HOUSE,"
14-18, Bloomsbury Street, W.C.1
Female fitters in attendance Monday to Friday.
Orthopaedic Mechanician Wednesdays only.
By Appointment.

The above Belt is quite an improved form with a deep back, giving good lumbar support, and obviating the use of perineal straps.

DECADES OF EXPERIENCE ENDORSE VAPO-CRESOLENE AN ANTISEPTIC INHALANT

For over 50 years physicians have prescribed the Vapo-Cresolene principle of inhalation as an effective means of treating certain respiratory affections. These cresols of coal-tar, antiseptic, yet harmless when vaporized, relieve paroxysmal cough and dyspnoea as in Whooping-Cough, Catarrhal Croup, and Bronchial Asthma, Cough in Broncho-pneumonia, and the bronchial symptoms of Scarlet Fever and Measles.

The method of vaporization is particularly adapted to treating bronchial infections in very young children. Laboratory tests under sick-room conditions show these vapours to be destructive to pathogenic bacteria.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

TYKEFORD ABBEY, NEWPORT PAGNELL,

BUCKS.

FUNCTIONAL NERVOUS DISORDERS, MEDICAL & CONVALESCENT CASES.

An Approved Nursing Home for reception of Female Cases under the Mental Treatment Act.

The Home is a Mansion of Historical interest, standing in 9 acres of garden and grounds, and is situated 14 miles from Northampton, and 12 miles from Bedford on the main London to Northampton Road, fifty miles from London. Both sexes are accommodated. Psychotherapeutic Treatment is used extensively in suitable cases. Radiant Heat, X-Ray, and Ultra-violet Light, Diathermy and Foam Baths. Billiards, tennis, etc. Fees from five gns. per week.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham. *Station:* Eden Park (Southern Railway). *Telephone:* Springpark 1180-1181

President: LORD WAKEFIELD OF HYTHE, C.B.E., LL.D.
Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.
Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds. Applications can be considered on behalf of patients of the educated classes in a presumably curable condition. With a view to early treatment voluntary or uncertified patients are admitted.

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.

Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this unit is found the X-ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.

Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms, and Occupational Therapy under competent instruction is encouraged.

In addition to the Resident Medical Staff, Consultants in special branches of Medicine and Surgery are available whenever required.

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.

For forms and further particulars apply to the Physician-Superintendent at the Hospital.

THE OLD MANOR SALISBURY

A Private Hospital for the Care and Treatment of those of both sexes suffering from MENTAL DISORDERS.

Extensive grounds. Detached Villas. Chapel. Garden and dairy produce from own farm. Terms very moderate.

COUNTY COUNCIL OF MIDDLESEX.

OPHTHALMIC SURGEON.

The County Council invites applications for the appointment of Ophthalmic Surgeon (part-time) for work at ophthalmic clinics established by the County Council at Southall, Southgate and Wembley for the treatment of visual defects and diseases of the eye occurring amongst children attending schools under the control of the County Council, and women and children residing in the County Council's area for Maternity and Child Welfare purposes.

The possession by applicants of the F.R.C.S. or D.O.M.S. diploma will be an additional recommendation.

The person appointed will be required to attend for one session (of about two hours per week during the school terms at each of the above-mentioned ophthalmic clinics. Remuneration will be at the rate of £2 12s. per session. The appointment will be held during the pleasure of the Council, and subject to three months' notice on either side.

Applications stating (1) name, (2) age, (3) qualifications and experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than January 23rd.

No special application forms are provided. Envelopes must be endorsed "Ophthalmic Surgeon." Canvassing, directly or indirectly, will be a disqualification.

ERNEST S. W. HART,
Clerk of the County Council.

Middlesex Guildhall, S.W.1.
January 3rd.

CITY OF MANCHESTER.

PUBLIC HEALTH DEPARTMENT.

WITHINGTON HOSPITAL AND INSTITUTION.

APPOINTMENT OF TWO ASSISTANT MEDICAL OFFICERS.

The Public Health Committee invites applications from qualified Medical Men for the positions of Assistant Medical Officers at the Withington Hospital (1,290 beds) and Institution (1,200 beds), Nell Lane, West Didsbury, Manchester.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous hospital experience.

The Hospital is a recognized training school for nurses and is equipped with all modern hospital requirements.

Salary for each appointment, £275 per annum, subject to a temporary deduction of £7 10s. per annum. The amount payable is, therefore, £267 10s. per annum, with board, residence, and laundry in addition, subject to the terms and conditions of the Manchester Corporation Grading Scheme. No bonus.

The appointments will be made, in the first instance, for a period of six months. The successful candidates, however, will be eligible for re-appointment for a further period of six months at the end of that period.

Applications, stating fully the age, training, qualifications, and experience of the candidates, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Withington Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Saturday, January 21st.

The candidates appointed will be required to commence duty as soon as possible after appointment, to devote the whole of their time to the duties of the positions, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

Town Hall, Manchester. F. E. WARBRECK HOWELL, Town Clerk.

January 9th, 1933.

DERBYSHIRE EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer (male) at a salary of £500, rising by annual increments of £25 to £700 per annum, subject to a temporary economy reduction, together with reasonable travelling expenses.

Candidates must be registered Medical Practitioners of at least three years' standing. The duties will include work under the Maternity and Child Welfare Service. Experience in this work, the administration of anaesthetics, and Mental Deficiency is desirable.

The appointment will be a designated post under the Local Government and Other Officers Superannuation Act, and the successful candidate will be required to pass a medical examination.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office, and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Thursday, January 26th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months notice on either side.

New County Offices, St. Mary's Gate, Derby. W. M. ASH, School Medical Officer.

January 10th, 1933.

CITY AND COUNTY OF NEWCASTLE-UPON-TYNE.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited from registered medical practitioners holding a Diploma in Public Health for the appointment of Assistant Medical Officer of Health. Salary £750 per annum, rising by annual increments of £50 to £900, subject to a temporary reduction on the commencing salary of £27 16s. 3d. The successful applicant will be required to contribute to the Council's [illegible] Superannuation Fund. Previous resident servi[illegible]ses Hospital is an esse[illegible]

Applications, on the prescribed form, which can be obtained on application to the Medical Officer of Health, Town Hall, Newcastle-upon-Tyne, must be submitted not later than Wednesday, January 25th.

January 9th, 1933.

BOROUGH OF EALING.

MATERNITY AND CHILD WELFARE SERVICES.

SECOND WOMAN ASSISTANT MEDICAL OFFICER.

Applications are invited from duly qualified Medical Practitioners for the position of Second Woman Assistant Medical Officer.

The duties will mainly consist of work in connection with the Council's Maternity and Child Welfare Scheme, embracing attendance at the Health Centres, School Medical Inspection and medical attendance on patients in the Chiswick and Ealing Maternity Hospital as Deputy Medical Attendant.

Applicants must have had previous experience of maternity and child welfare and school medical work and of work in a Maternity Hospital.

The person appointed will be required to devote her whole time to the duties and will not be allowed to engage in private practice.

The salary will be at the rate of £600 per annum, rising by £25 per annum to a maximum of £700. A deduction of 5 per cent. will be made in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to the candidate passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application form and terms of appointment can be obtained from Dr. THOMAS ORR, Medical Officer of Health, Town Hall, Ealing, W.5, to whom applications, accompanied by copies of not more than three recent testimonials, must be delivered not later than 9 a.m. on January 23rd.

Town Hall, Ealing, W.5. GEO. E. BRYDGES, Town Clerk.

WEST SUFFOLK COUNTY COUNCIL.

ASSISTANT COUNTY MEDICAL OFFICER AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for the above whole-time appointment (men or women) which includes duties in School Medical Inspection, Maternity and Child Welfare, Tuberculosis, Venereal Diseases, etc., work. Applicants must be registered Medical Practitioners and not exceed 35 years of age, preferably holding the Diploma in Public Health. Salary £500 per annum, rising by annual increments of £25 to a maximum of £700 plus travelling allowance. Particulars of appointment and forms of application may be obtained from the undersigned, by whom applications, accompanied by copies of not more than three recent testimonials, must be received not later than January 30th.

Canvassing in any form, direct or indirect,

L. G. H. MUNSEY, Clerk of the County Council.

CITY OF LIVERPOOL.

CITY INFECTIOUS DISEASES HOSPITALS.

ASSISTANT RESIDENT MEDICAL OFFICER.

The Port Sanitary and Hospitals Committee of the Council of the City of Liverpool invite applications for the above office. Salary £200 per annum, together with board, residence, etc. (subject to a temporary deduction as authorised by the Council).

The appointment is for a term of not exceeding one year and is not renewable.

Every candidate will be required to possess a registered Medical and Surgical qualification, and should have a knowledge of Bacteriological methods.

The person appointed will not be allowed to engage in private practice, and will be required to devote whole-time service to the duties of the office.

Applications to be made upon forms obtainable from the Medical Officer of Health, Municipal Annexe, Dale Street, Liverpool, to be endorsed "Resident Assistant Medical Officer," and returned to the undersigned so as to be received not later than 10 a.m., Monday, January 23rd.

Municipal Buildings, Liverpool. WALTER MOON, Town Clerk.

January 11th, 1933. By Order of the Council. G. C. ANDERSON, Medical Secretary.

WEST LONDON HOSPITAL, Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of ASSISTANT GYNAECOLOGIST.

Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh, or Ireland, or a Fellow or Member of the Royal College of Physicians of London. The successful candidate will be required in addition to his other duties to undertake such teaching for the Post-Graduate College as the Board may approve.

Applications, accompanied by copies of testimonials, should reach me not later than Thursday, February 2nd. Candidates must attend a Special Meeting of the Medical Council on Friday, February 3rd, at 4.30 p.m. and prior to that date call upon and send copies of applications and testimonials to each member thereof. They must not canvass Members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and if so notified, be in attendance at a Special Meeting of the Board at 5.30 p.m. on Tuesday, February 7th, when the election will be made.

H. A. MADGE, Secretary.

LONDON JEWISH HOSPITAL, Stepney Green, E.1. (General Hospital—108 Beds.)

The Council of Management invite applications for the post of SECOND RADIOLOGIST. Candidates will be required to attend the Department on two half days each week. They should send twenty copies of their application, with copies of three recent testimonials, to the Secretary at the Hospital before Friday, January 27th.

WEST LONDON HOSPITAL, Hammersmith Road, W.6. (234 Beds.)

Required, a Non-Resident CASUALTY OFFICER (male). The appointment is tenable for one year from February 1st next, subject to one month's notice on either side. The appointed candidate will be eligible for re-election for two further periods of one year. Salary at the rate of £250 per annum, with lunch and tea daily.

Candidates must be duly qualified registered Medical Practitioners, and preference will be given to those who have held a resident appointment in a General Hospital. Applications (which must be made on printed forms obtained from me) must reach me not later than Thursday, January 19th, 1933. Selected candidates will be required to call upon such members of the Medical Staff as directed, and to be in attendance at a Meeting of the Medical Council at 4.30 p.m. on Friday, January 27th, and the House Committee Meeting at 5 p.m. the same day, when the appointment will be made.

H. A. MADGE, Secretary.

Visits 5/- upwards. Very little midwifery at 5 to 10 guineas. Expenses low. Excellent and well-built house, ideally situated, having ample accommodation (surgery, *waiting* room, and dispensary, 3 reception, 5 bedrooms, etc.). Rent on lease £120. Premium £2,500. Good educational facilities.
6. EGYPT.—Well-established PRACTICE, producing about £960 p.a., and offering good scope for increase. Fees 10/6 to 2 guineas. Excel*lent accommodation can be rented at £16 10s. monthly. Premium* to include all furniture, drugs, drug bottles, instruments, etc., £2,000.
7. YORKSHIRE.—PARTNERSHIP.—A one-fourth share, with increase, later, is offered in a very sound old-established general Practice, situated in favourite country town, within easy reach of coast. Gross cash receipts for the last three years have averaged £3,700, and for the immediate past twelve months £4,180. Panel of 2,000, and appts. bring in about £500 p.a. Fees 5/- to 21/-. House contains 3 reception, 5 bedrooms, etc. Electric light; garden. Garage. Can be rented at £46 p.a. Or other houses available. Excellent sport and good schools. Premium for share 2 years' purchase.
8. CHESHIRE.—NEAR COAST.—Old-established middle and working-class PRACTICE, averaging for the past three years over £1,300. Panel of 550. Fees from 3/6. Good house, with 3 reception, 7 bedrooms, etc. Price for freehold £1,200, part on mortgage.
9. PARTNERSHIP.—ANGLO-WELSH BORDER.—A one-third share, with increase later, is offered in an *old-established good mixed Practice,* situated in pleasant country town, amidst beautiful surroundings. Gross cash receipts for last 12 months £1,800, of which £800 is from panel and appts. Purchaser should be interested in medicine as Vendor undertakes surgery. Suitable accommodation obtainable. Premium £900, part by instalments if desired.
10. *SOUTH* [illegible] *ENGLAND.*—LARGE TOWN.—ASSISTANTSHIP with vi[illegible] Practice is very well established, chiefly [illegible] panel. Fees 3/6 to 10/6. Ingoing Partner should be between 24 and 26 years of age, with good Hospital experience, etc. and Public School education. Suitable house available during preliminary assistantship.
11. *SOUTH CORNWALL.—Old-established* unopposed PRACTICE, situated in very pleasant district, with mild climate. Gross cash receipts approximately £950 to £1,000 p.a., including £275 from panel and appointments. Fees 5/- to 7/6. Very nice house, *overlooking the* sea, containing 3 reception, 4 bedrooms, 2 maids' rooms, bathroom, etc., and professional accommodation. Garage. Garden. Freehold for sale, £300 down, and balance on mortgage. Premium £1,400, to include drugs, etc. Good scope for increase.
12. CHANNEL ISLANDS.—*Well-established better-class PRACTICE,* averaging over £600 p.a. Good fees. Not much midwifery, but scope for this work if wished. Suitable house on rental. Moderate premium.
13. NORTH DEVON.—Very old-established unopposed country PRACTICE, *in beautiful district, within easy reach of the sea. Cash receipts* over £900, including *panel and appointments about £300. Excel*lent residence (3 reception, 6 bedrooms, bathroom, etc.). About half an acre of garden, tennis lawn, etc. Garage. Water laid on and main drainage. Rent on lease £60 p.a; *Premium £1,450. Good* hunting, shooting, fishing. Educational facilities.
14. *SOUTH-WEST OF ENGLAND.*—Coast Town.—Middle and working-class PRACTICE, rapidly increasing, and producing about £600 p.a., including panel of 400. House can be rented at £75 p.a., and contains 2 reception, 5 bedrooms, etc. *Electric light. Garden. Prem. £750.*
15. SURREY.—Growing residential neighbourhood, within easy reach of London.—Mixed-class PRACTICE, *producing about £1,000* p.a., and offering good scope. Panel of 400. Fees from 3/6. Suitable house with 2 *reception,* 3 bedrooms, etc. Price for freehold £1,400, part *on mortgage. Premium* 2 years' purchase.
16. PARTNERSHIP.—NORTHERN COUNTIES.—A one-third share (with increase later) is *offered in a good middle-class non-panel Practice,* situated in a prosperous town, with pleasant surrounding country. Gross cash receipts average about £3,500 p.a. Fees 3/- upwards. *Suitable house, with* 2 reception, 4 bedrooms, etc., and small garden. Price £1,200, part on mortgage. Excellent sport and educational facilities. Premium for share, £2,000.
17. KENT.—Good-class NUCLEUS, non-dispensing, in pleasant residential district within 20 minutes' run of London. Receipts between £350 and £400, and *offering exceptionally* good scope. Fees 10/6 to 21/-. Good house, ideally situated, with ¾ of an acre of garden, tennis court, etc. Price freehold £2,800, to include premium for Practice. Excellent educational facilities.
18. MIDDLESEX.—Residential District.—Mixed-class PRACTICE, averag*ing £537 p.a., including panel of 150.* Fees from 3/6. Corner house, with 2 reception, 5 bedrooms, and professional accommodation, *with* separate entrance. Freehold. Golf and other sport. Very good schools. Price for practice and house £2,100, or near offer, part on mortgage.
19. *PARTNERSHIP.—LONDON, SOUTH-WEST.—A one-half share is* for disposal in an old-established very good middle-class Practice, in pleasant residential open suburb, within easy reach of City and West End. Average gross cash receipts for past 3 years £2,557. Panel of 1,400. Visits from 4/-. Not much midwifery, from 3 to 7 gns. House contains 2 reception, 6 bedrooms, etc., and professional rooms. Garden. Good schools and sport. Premium £2,559.
20. WESTERN SUBURB. — Old-established and mainly middle-class PRACTICE, worth about £400 p.a. and offering scope. Panel of 108. Visits 3/6 to 21/-. Midwifery 3 gns. upwards, not encouraged. Good house (6 bedrooms, etc.) with very nice garden and garage. Price leasehold (42 years to run) £1,850, £1,200 on mortgage. Premium moderate.
21. NEW ZEALAND (*North Island*).—*Old-established* non-dispensing PRACTICE, situated in increasing county town, amidst beautiful surroundings. Cash receipts for past five years average £1,400 p.a. Attractive residence standing in an acre of garden, with tennis court, orchard, etc. Electric light. Can be leased. Educational facilities, *sport, etc. Premium* £1,000.
22. SANATORIUM.—SOUTH-WEST OF ENGLAND, and within 20 miles of County Town. Very old-established. Receipts for the past three years average over £9,000 p.a. Patients middle and upper class. Accommodation for 45. Price for goodwill, freehold house, with large *grounds,* furniture, fixtures, etc., is moderate.
23. MANCHESTER. — Suitable Lady Doctor. — Middle and working-class PRACTICE, averaging £670 p.a., including panel of 450. Fees 2/6 to 7/6. House contains 3 reception, 5 bedrooms, separate surgery entrance, etc. Bathroom. Electric light. Garage. Rent on lease £80 p.a. Premium 1½ years' purchase. Very large scope for increasing the Practice as Vendor has only worked it as a part-time one.

ASSISTANTS REQUIRED.—(1) MIDDLESEX. [illegible] PRAC. TICE, with substantial panel and *good* app[illegible] with view to Partnership. Suitable hou[illegible] English and well-experienced. *(2) HANTS.—Large Town. Indoor,* salary £300 p.a. (3) WALES.—Indoor £300 p.a.; previous experience not required. (4) SOUTH WALES.—Outdoor; £300, with rooms and attendance.

WANTED TO PURCHASE.

1. LONDON, or within twenty miles.—Good mixed-class PRACTICE, with panel of about 1,500. Income £1,200 to £1,500. Fair-sized house and garden.
2. LONDON SUBURB or good Provincial Town.—Better-class PRACTICE averaging about £1,500 to £2,000 p.a., *with fair-sized panel. Small* house sufficient. Ample capital.
3. SOUTH OF ENGLAND or RESIDENTIAL SUBURB OF LONDON.—Chiefly better-class Practice, offering scope for developments. Substantial panel required. Nice house and garden. Ample capital for suitable practice or partnership.
4. LONDON or SUBURBS, preferably West or South-West.—PRACTICE or PARTNERSHIP producing about £1,200 p.a. or less if *scope.* Fair-sized house with garden.
5. *MIDLANDS OR SOUTH OF ENGLAND* (not Devon or Cornwall).—Country PRACTICE bringing in from £750 to *£800 p.a. Small* house to rent, with good grounds. Must be within reach of good fishing.
6. MANCHESTER or SUBURBS.—Well-established PRACTICE, in pleasant district. Income from £1,600. Good panel essential. Capital avail.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. *Full details on application.*

VENTRICULIN WITH IRON

In the Treatment of Secondary Anaemia

VENTRICULIN, the desiccated preparation of gastric tissue prepared by Parke, Davis & Co., has proved highly satisfactory in the treatment of pernicious anaemia. It possesses the power to stimulate the haematopoietic system in anaemia of the secondary type also.

Iron in adequate quantities, to assist in building up the depleted haemoglobin, has long been recognized as an important element in the treatment of secondary anaemia, and research work of recent years has emphasized its value.

The advantage of associating iron with Ventriculin in secondary anaemia has been confirmed by clinical experience, and in order to provide a convenient form for the simultaneous administration of Ventriculin and an effective iron salt, Parke, Davis & Co. have introduced

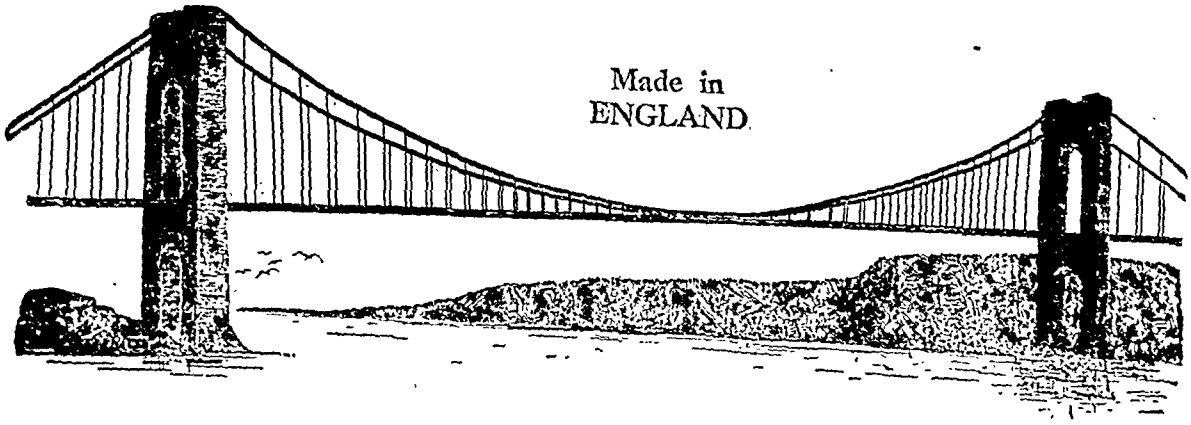
VENTRICULIN WITH IRON.

This preparation, which combines 12½ per cent. of ferric citrate with Ventriculin, has been shown clinically to be effective in cases of secondary anaemia.

Ventriculin with Iron is supplied in bottles of 100 grammes. Each bottle is fitted with a metal measuring-cap. The dose is from 10 to 20 grammes daily.

PARKE, DAVIS & CO., 50 BEAK STREET, LONDON, W.1.

Laboratories: Hounslow, Middlesex. Inc. U.S.A. Liability Ltd.



Bridging the Crisis

IN all the Pneumonias, when the vitality is low and the heart is weak, the application of an Antiphlogistine Dressing is often the bridge which will ease the discomfort and so enable the patient to pass the crisis and to reach safely the point of resolution.

Not only is there a prompt assuaging of the pain, but dyspnœa is relieved, the action of the heart improved and a general soothing of the patient with induction of sleep follows, as the result of the relaxant effects which an Antiphlogistine Dressing affords.

Its application is simple and because it retains its potency for 24 hours, it ensures against unnecessary handling and disturbance of the patient.

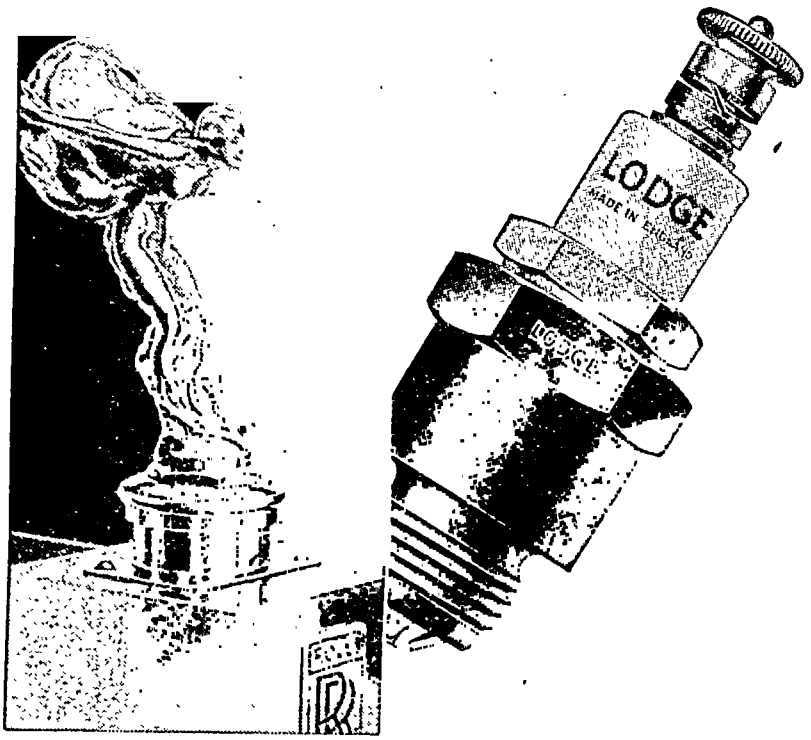
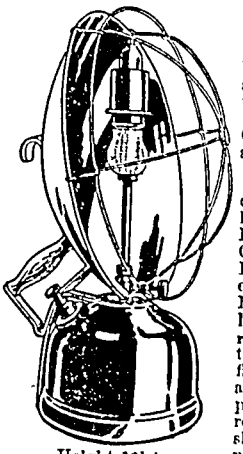
PLUGS



THE TILLEY RADIATOR
AS A SOURCE OF RADIANT ENERGY
FOR TREATMENT OF DISEASE



Height 16½ in.

Medical experience has shown that the infra-red rays emitted by sources of heat have a beneficial effect in the treatment of painful affections, such as Chronic Rheumatism and Neuritis.

Carrying out tests on various sources of heat at the London Light and Electrical Clinic, Sir Leonard Hill found that the emission of the Tilley Radiator was **particularly rich in infra-red rays**, which penetrate the skin and excite flushing and other reactions which relieve pain. To secure these results the Radiator should be brought as near to the painful part as can comfortably be borne. Exposure to the rays may be prolonged safely for half an hour or more.

Here, then, is convincing proof of the usefulness of the Tilley Radiator in every home—not only for the genial heat it provides, but also for the benefits which can be obtained by its use medically.

Its portability and absence of connections make the Radiator eminently adaptable to all circumstances.

BRITISH MADE THROUGHOUT.

The price of the Tilley Radiator is 45/- Enquire Local Ironmonger. If any difficulty, Radiator will be sent post free on receipt of remittance, or C.O.D., post and charges paid.

THE TILLEY LAMP CO. (Dept. 14)
HENDON, N.W.4.

"INTESTINAL CORRECTION" HERBARAS plant seeds are a specially selected perfectly sterilised species of the plantago family. The medical profession can prescribe them with confidence in cases of chronic constipation. "NEW HEALTH" (Organ of the "New Health Society") says: "The Herbaras plant seeds are very tiny, and when soaked in water swell up into a soft jelly—gently sweep along the walls of the intestines—collect the waste matter—leaving a clean and healthy bowel." Samples will be sent to any physicinn on request. Address Mr. JOHN W. LONGMAN, Foreign Produce Merchant and Importer, Clyde House M., 489a, Oxford Street, London, W.1.

METHODS AND USES OF HYPNOSIS AND SELF-HYPNOSIS.
By BERNARD HOLLANDER, M.D. 6s.

By the same Author:
BRAIN, MIND, AND THE EXTERNAL SIGNS OF INTELLIGENCE.
Profusely Illustrated. 12s. 6d.

MEDICAL PRESS:—"Dr. Hollander has a deserved reputation as an original and independent thinker. His present book will increase that reputation."

Charged up for the Winter!

STARTING is harder in winter time. Your battery must be fit, full of "pep," or your "get away" will be sluggish. You'll want more lighting too, and your battery must be ready for it.

Now, however, the advent of the new WESTRIC CHARGER makes it possible for all car owners with alternating current in the garage to keep their batteries always charged at a cost as low as 1d. per night of twelve hours.

An illustrated folder B.M.J.2, giving full particulars, will be gladly sent on request.

Price complete for 6 and 12 volt batteries - 75/- nett.

WHEN WINTER *is upon us*—

HORLICK'S MALTED MILK Co. Ltd.
SLOUGH, BUCKS. *British Throughout*

Influenza and other winter ills make easy victims of those who are overtired and fatigued. For both doctor and patient it is imperative to use every means to increase resistance to infection. The newer knowledge of nutrition emphasizes the part that diet can be made to play in preventing and overcoming disease.

Horlick's Malted Milk contains 15% of easily digested protein, and 60% of malt sugar—maltose and dextrin. Researches have shown malt sugar to be of high biological value—"un sucre vivant et minéralisateur," as one scientist has expressed it. Horlick's also contains Vitamins A, B and D, and effective mineral salts.

Recent tests on human subjects show that Horlick's is not only easily digested and absorbed, but that it speedily affects metabolism—thus confirming the clinical experiences of doctors during the past fifty years.

Insufflators, price 3/6.

Also supplied in glass tubes and pocket distributors. 20% discount for doctors.

INFLUENZA

The best preventive to infection of the naso-pharynx, and a product the potency and reliability of which has been proved, is

DIMOL SNUFF

(or insufflation powder)

● Diluted with 10 times its bulk of mucus will kill B. influenzae in 30 seconds.

"Examination of a large number of patients on snuff treatment has shown that a healthier condition of the mucous membrane of the nose is induced, rhinorrhoea stops and crusting is prevented."

Vide L.C.C. Ann. Rept., 1930. Vol. IV, Pt. III (published 1932).

Prices and particulars will be sent on application to:

DIMOL LABORATORIES LTD., 40, LUDGATE HILL, LONDON, E.C.4.

Distributing Agents: SANGERS Ltd., 255, Euston Road, London, N.W.1

Extracts from bio-chemist's Report on

ROWNTREE'S COCOA

● "The finding in cocoa* of a protein which contains this essential amino acid is of great importance."

● "In the case of cocoa* an intensely acid juice is secreted, but this acidity is adsorbed by the proteins so that it is reduced in a very considerable degree."

● "A series of experiments have shown that the main 'buffering' power of cocoa* is due to the protein that it contains."

● "These investigations shed an entirely new light on the value of cocoa* as a digestive beverage."

★ *"Cocoa" refers to Rowntree's Cocoa*

Victoria 2041. *"Taxolabs, Sowest, London."*

THE SPECIAL CEREAL FOOD DESCRIBED IN THE *"BRITISH MEDICAL JOURNAL,"* *JANUARY 14th,* IS MADE (WITH ADDED VITAMIN D) IN ENGLAND UNDER THE NAME OF *FAREX*

PRODUCT OF THE GLAXO LABORATORIES

This cereal food, rich in minerals and vitamins A, B_1, B_2, and D, solves for the first time the problem of ensuring to infants an ample supply of all the dietetic elements essential for their healthy growth and nutrition. The "refined" cereals now generally in use are demineralized and practically devoid of vitamins.

Addition of FAREX to the diet may begin round about the fourth month. Its effect on nutrition and the contrast in growth between children on the reinforced cereal and those on ordinary cereals are admirably brought out in the above-mentioned paper.
Literature and samples of Farex will be sent on request.

GLAXO LABORATORIES, 56, OSNABURGH STREET, LONDON, N.W.1

"SONERYL"

Trade Mark

BUTOBARBITAL

POWERFUL HYPNOTIC & ANALGESIC

An agent which has the double advantage of relieving pain and inducing sleep is invaluable in everyday practice.

"Soneryl" adequately meets this need and is widely employed for insomnia, whether arising from painful affections or febrile or nervous states.

"Soneryl" produces no after-effects nor does it lead to habit formation.

Supplied in tablets.

Write for descriptive literature and sample.

Prepared in the Laboratories of

MAY & BAKER LTD.

BATTERSEA LONDON, S.W.11

CHLOR-SAN

A STABLE SOLUTION of Sodium Hypochlorite in Salt Solution, containing approximately 1% of available Chlorine. A household antiseptic for personal and domestic use, which, when used in accordance with the directions, is non-caustic and non-poisonous. Purifies, disinfects, deodorises, is economical in use, keeps indefinitely. An excellent prophylactic against throat and mouth infections.

IDEAL FOR ARTIFICIAL TEETH.

Full size trial sample free to any medical practitioner, in Great Britain ONLY, on application by postcard to BOOTS THE CHEMISTS, STATION ST. NOTTINGHAM.

For Influenza and Post-Influenzal Debility

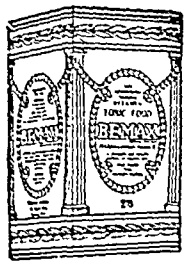
It is recognised that the severe debility especially of the heart and digestive organs which follows influenza, yields most readily to a dietary rich in vitamins. The simplest way to secure this condition is by augmenting the ordinary diet with BEMAX.

BEMAX is a natural vitamin food prepared from the de-toxicated embryo of selected cereals. It is the richest known source of Vitamin B and contains also Vitamins A and E with valuable salts of Phosphorus.

Both as a preventive of influenza during times of epidemic, and as a restorative food during convalescence BEMAX has proved to be invaluable. Definite improvement is usually observed soon after its use.

BEMAX is a pleasant food to take, very easy to assimilate and digest. It will be taken readily even in those influenza cases where gastric symptoms predominate.

Laboratory reports on BEMAX and a clinical sample for personal trial will be sent to any medical man on receipt of his professional card.



BEMAX

THE RICHEST NATURAL VITAMIN TONIC FOOD

THE BEMAX LABORATORIES, 23, UPPER MALL, LONDON, W.6.

accepted as a distinct advance

for economy and palatability

THE ECONOMICS OF PERNICIOUS ANAEMIA

The preparation presented before the combined section of Therapeutics and Medicine of the Royal Society of Medicine on January 10th (and earlier in the series described in the "British Medical Journal"*) is now available to the medical profession under the name Filivex.

Filivex, both in its effect on the blood condition and on the patient's symptoms, acts at least as promptly and effectively as extracts from mammalian liver.

No less important is the fact that Filivex is far and away the cheapest potent liver extract offered to the medical profession.

Further data about this new product, which is available both as a powder and a liquid, will be supplied on request.

LIQUID
In 8-oz. bottles, 5/-.
Each fluid oz. of Filivex is therapeutically equivalent to the extract from 4 oz. of fresh mammalian liver.

POWDER
In boxes of three tubes, 4/-.
In boxes of twelve tubes, 14/6.
Each tube contains Filivex therapeutically equivalent to the extract from 8 oz. of fresh mammalian liver.

GLAXO LABORATORIES, 56, OSNABURGH ST., LONDON, N.W.1

The saving on even the cheapest mammalian extract available in this country is in the order of several pounds a year; and it should be added that this calculation implies a patient with a very low maintenance dose.

* *British Medical Journal August 20th*, 1932, *p.* 347.

'PANOPEPTON'

AS A RESTORATIVE FOOD.

'PANOPEPTON' presents, in a form ready for absorption, the entire nutritious substance of beef and wheat. It is a complete solution of all the nutrient, savory, and stimulant nitrogenous and inorganic constituents of these typical foods.

Supplied in 12-oz. bottles.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.)
NEW YORK, and 65, Holborn Viaduct, LONDON, E.C.1.

'Zymine' Peptonising Tubes

FOR THE PREPARATION OF PEPTONISED MILK AND OTHER PREDIGESTED FOOD for the SICK

Peptonised Milk prepared with 'Zymine' Peptonising Tubes is a perfectly digestible and absorbable food. Its use precludes all accumulation of unassimilable matter in the intestinal tract.

Supplied in boxes containing 6 and 12 tubes.

Agents:
Burroughs Wellcome & Co.,
LONDON, SYDNEY, and CAPE TOWN.

VICHY-CÉLESTINS

THE WORLD-RENOWNED NATURAL MINERAL WATER

FERMENTATIVE DYSPEPSIA

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Célestins,** by its slightly stimulating action, clears out the stomach, and thus avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

NATURAL VICHY SALT for Drinking and Baths.

VICHY DIGESTIVE PASTILLES prepared with Natural Vichy Salt.

OVALTINE

WHEN SLEEP IS DIFFICULT

Judged by the numerous reports received from physicians and also from grateful patients, the use of "Ovaltine" for ensuring sound refreshing sleep deserves the widest recommendation.

It has been remarked that a more helpful prescription could not be wished for because:

1. Taken last thing at night before retiring it exercises a pronounced sedative effect and one that is natural in every sense.
2. It has a pleasantly soothing action on the stomach and nervous system, and does not cause the slightest digestive unrest, or occasion constipation.
3. It promotes a sufficiency of healthful sleep without resource to hypnotic drugs.

"Ovaltine" is a delicious concentrated extraction of malt, milk, and eggs, in the form of golden granules, which dissolve instantly in milk.

A liberal supply for clinical trial sent free on request.

100% EFFICIENCY IN HOSPITAL & PRIVATE PRACTICE

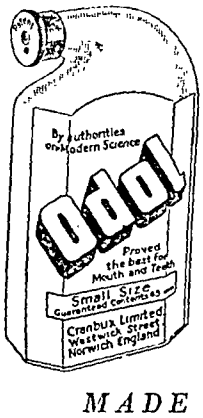
How ODOL serves the Dental Profession

A Sheffield Dentist writes :—

"During my hospital work I find ODOL a necessity for my own personal safeguard. I have found it extremely useful for scaling operations, also for cleansing teeth in association with pumice. After devitalisation of the pulp I preferably use ODOL in place of pure Carbolic Acid or Phenol for its antiseptic properties. I use ODOL now personally and recommend same to patients and friends. Your Dentifrice possesses very high cleaning properties."

ODOL IS INVALUABLE AFTER EXTRACTIONS

PROMOTES RAPID HEALING—SOOTHES WHILE IT CLEANSES



Daily use of ODOL is essential to sound oral hygiene. Patients, especially children, appreciate its refreshing flavour and pleasant perfume.

Generous samples of ODOL preparations will be sent free on application to CRANBUX Ltd., Norwich.

(This offer does not apply to countries abroad or the I.F.S.)

After Influenza

The Effective Tonic is "BYNIN" AMARA

The general action of "Bynin" Amara is manifested by increased tone of the nervous, muscular and cardio-vascular systems. It stimulates the digestive organs, improves the flagging appetite, corrects anæmia and aids nutrition generally. The marked asthenia and nervous depression which are prominent features of the post-influenzal state, yield rapidly to its influence. A course whenever there is any indication of lowered resistance is a valuable safeguard against infection.

In bottles at 2/-, 3/6, 6/6 and 12/-

MEDICINE-MAN OF CENTRAL AUSTRALIA.—The illustration shows a member of the second degree of medicine men. With charcoal and fat he paints a broad band across the bridge of his nose, and has drawn for him, upon the chest, shoulders and abdomen, the sacred design of the spirits in whose school he has qualified. The sign on his forehead represents the spirit's hand. He wears also a nose bone passed through the septum; this, however, is not one of the distinguishing features of a medicine man, but is worn by many among the laity. During his year of probation he visits other medicine men who initiate him in the secret rites and practices of the profession.

Observations
ON
EXOPHTHALMIC GOITRE*
BY

W. H. C. ROMANIS, M.A., M.B., M.CH.CANTAB., F.R.C.S.
SURGEON TO ST. THOMAS'S HOSPITAL AND TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST

Exophthalmic goitre is a mysterious disease, and of its pathology we are very ignorant. We know many isolated facts about its causes and onset, but it is difficult to correlate these and to give each fact its proper position in the aetiology of the disease. Thus there is little doubt of the correctness of the following facts, though they advance us very little in assigning a true pathological cause:

The disease is far more common in women than in men, in blondes than in brunettes, and in single women than in married ones.

It almost always causes more enlargement of the right side of the thyroid than of the left.

It exhibits a slight tendency to frequency in certain parts of the world, but these localities are not usually those where ordinary parenchymatous goitres abound.

It is rarely seen at the extremes of life, being uncommon under the age of 15 and over the age of 55.

It seems to be rather commoner in some professions and walks of life than in others. School teachers exhibit a marked tendency to develop it, and it is certainly seen more in brain workers than in manual workers, while it also tends to produce a type of woman who is volatile, lively, and temperamental, and who, if the disease is not too far advanced, is usually of a type distinctly attractive to the male.

These are all mere unexplained facts, but there are other features of which we are tolerably certain. Thus, most of the symptoms and physical signs are due to a substance produced in the thyroid gland, which is nearly always enlarged. This substance is either an altered and toxic secretion, or possibly an excessive amount of normal secretion. The thyroid gland, therefore, may be looked upon definitely as the factory where the symptoms are produced. That there is, however, some underlying primary cause responsible for the changes in the thyroid gland itself cannot be denied, and there is a considerable body of evidence pointing to an infective causative agent of some sort—possibly intestinal. In support of this is the fact that in many cases the patient dates the onset of the disease from some kind of febrile attack, often referred to as "influenza," while it is not uncommon to find the spleen definitely enlarged. There is, however, so far no proof of the existence of this infective agent. There is also very little doubt that the other ductless glands are involved in the process, and play a certain part in the production of the symptoms; the suprarenals especially are important in this connexion, and it is quite possible that some of the physical signs, such as the exophthalmos, are directly due to suprarenal influence. The thymus also is nearly always found to be enlarged. Again, it is not uncommon to find a direct connexion between this disease and diabetes, and the two conditions may exist together. However this may be, in the present state of our knowledge we believe that these other ductless glands are affected secondarily to, or possibly as a compensation for, the state of the thyroid, and that it is the alteration in the thyroid gland itself that is the basis of the disease.

DEFINITION

It is very important in any discussion of this disease to remember that a correct definition of the term "exophthalmic goitre" is difficult, that between the ordinary parenchymatous goitre with no toxic symptoms, the simple thyroid adenoma with nervousness, tremor, and rapid pulse, and the well-marked case of Graves's disease with its classical syndrome, there are an infinite number of different grades of severity, and that occasional clinical curiosities are found, such as: marked toxic hyperthyroidic symptoms with no appreciable enlargement of the thyroid gland; unilateral exophthalmos instead of the common bilateral type; or—by no means uncommonly—malignant disease of the thyroid, associated with exophthalmos, palpitation, rapid pulse, tremor, and nervousness. I do not, therefore, regard any case as deserving of the name of Graves's disease unless it presents a certain amount of eye change, a rapid pulse, and definite cardiac changes—slight enlargement in the milder types, and considerable dilatation, with fibrillation and alterations in the heart sounds, in the more advanced cases. Moreover, in all cases in which these toxic symptoms are mild enough to raise any doubt as to whether the condition should really be called Graves's disease or not, before the diagnosis is actually settled a microscopical examination of the gland should be made to see if the hyperplasia and changes in the epithelium, which the exophthalmic thyroid gland always shows, are present.

Primary and Secondary Graves's Disease

The distinction between primary and secondary Graves's disease is undoubtedly a useful one, both in diagnosis and in treatment. By primary Graves's disease we mean that type where the toxic symptoms have been present from the first, and more or less coincide with the appearance of the goitre, while secondary Graves's disease is the name applied to those not at all uncommon cases where a goitre (either adenomatous or parenchymatous) has been present for some time—often many years—before the full range of toxic symptoms comes on. Primary Graves's disease is usually much the more severe form, and it is usually in this class that the desperately bad cases are found. Secondary Graves's disease shows a particularly marked tendency to give rise to auricular fibrillation, but the results of operative treatment in secondary Graves's disease are even better than those in primary cases, even though marked auricular fibrillation be present. It is possible, or even probable, that in primary Graves's disease we are dealing with an altered and toxic thyroid secretion, and in secondary Graves's disease with an excess of a normal thyroid secretion.

When discussing exophthalmic goitre, therefore, it is best to refer only to the true Graves's disease, and not to such conditions as cysts or adenomata of the thyroid, with nervousness and a rapid pulse, or to parenchymatous goitres in nervous women. The true Graves's disease is naturally a very much more serious condition.

The cases one encounters clinically vary considerably, according to whether the main stress of the disease falls upon the nervous system, the cardiac system, or the abdominal organs. Marked affection of the nervous system, with tremors, jumpiness, excitability, and even mental changes, seems often to be associated with marked exophthalmos and a large, very hard, rounded, prominent goitre, though it must be remembered that the goitre of Graves's disease never reaches the very large size which a parenchymatous goitre may attain. On the other hand, in the more truly cardiac type of case, where severe dilatation and fibrillation occur, the goitre is usually softer and less definitely prominent, while exophthalmos is less marked, but pigmentary skin changes are often present. The abdominal type of case with much diarrhoea and vomiting often appears to be intermediate between the above two types.

As regards eye changes, though the exophthalmos is often very marked, there is a very early change sometimes seen in the eye before any prominence of the eyeball or von Graefe's sign is present, which is, I think, almost certain evidence that eye changes are commencing; and this is a peculiar shininess or glinting of the cornea, which is often noticeable at some little distance from the patient.

* Extracts from a paper read to the Guildford Division of the British Medical Association.

CHOICE OF TREATMENT

Several methods of treatment exist, each of which has its own advantages, disadvantages, and risks. Briefly, we are faced by the possibilities of treatment by various medical methods, by *x* rays and radium, and by surgery.

While there is no doubt that exophthalmic goitre is a disease which is serious, grave, and unpleasant, it is by no means always necessarily fatal. It is difficult to estimate mortalities, but probably about 25 to 50 per cent. of cases of Graves's disease will ultimately die of it if left untreated, while of the remainder a few will undergo a spontaneous cure, though this will take many years and there may be relapses. The majority will develop into chronic invalids, liable to be carried off by any slight infection, able to hang on to their lives but unable to do anything with them, and these points must be taken into account in estimating both the value and the necessity of any particular form of treatment.

Medicine

Treatment by medical means can certainly offer a fair chance of a cure in early cases, and, in others, a very reasonable chance that, with a careful and sheltered life, the patient may live to a good old age. At the same time it will have to be very prolonged, and it is not likely that even mild cases will get well under several years, while the more severe the case is the less likely is any permanent benefit to accrue. Temporary benefit is nearly always produced by medical treatment in every type of case, but unfortunately relapses are only too frequent. In connexion with this it is remarkable that Lugol's solution of iodine, given in 10-minim doses, nearly always produces a marked improvement, which, however, only lasts for two or three weeks as a rule. Most surgeons, therefore, make a practice of giving Lugol's solution for ten days or so before any operative treatment is undertaken, but it should not be continued for longer than this.

X Rays and Radium

The results of *x*-ray treatment are not very impressive. It is uncertain and not free from the risk of producing myxoedema. It is undoubtedly capable of producing improvement in some cases, but cures are very rare indeed and relapses very common. Moreover, the surgeon cannot help having a personal objection to it, because he often has to operate upon cases which have previously received *x*-ray treatment, and the operation is rendered definitely more difficult because of the increased adherence and vascularity of the gland. There may be no more difficult operation in surgery than the removal of a thyroid which has previously had *x* rays on it. Radium, on the other hand, does seem to be more useful in specially selected cases. Where other methods of treatment have failed, or when operation is impossible, radium applied externally over the goitre has sometimes produced marked improvement. This has been especially so in cases which are showing mental changes.

Surgery

Surgical treatment has always seemed a reasonable procedure, and there is no doubt now that operations can be performed, even in severe cases, with a mortality that is very slight, and that they result in vast improvement in the patient's health. A recent series of 650 cases of Graves's disease, published in *St. Thomas's Hospital Reports*, has shown that the mortality of all cases treated in the surgical wards is about half that of all cases treated in the medical wards.

Many surgical procedures have been devised. Excision of the cervical sympathetic is quite useless, and ligature of one or more of the thyroid arteries is very seldom done now. There is a consensus of opinion among surgeons, which is shared by many physicians, that removal of very large portions of the thyroid gland is the procedure of choice; for though we do not know the primary cause of the disease—that cause which leads to the enlargement of the thyroid—there is abundant evidence that the enlarged thyroid is what we may call "the factory of the symptoms," and that by reducing its activity we can relieve these symptoms and render the patient a normal individual again.

CHOICE OF OPERATION CASES

One of the most important points to be considered is the selection of those cases in which operation is likely to be most suitable and successful. There are very few cases in which it is not advisable to prescribe a course of medical treatment first before considering operation. The mild cases may be cured by this, while the severe ones will become fitter and better, and more able to stand the operation. Among the last 900 cases I have seen there have only been three which have been refused the chance of operation on the ground that they were too advanced for surgery to hold out any hope of benefit. But there are many cases to be seen in which the symptoms are so slight that one may well wonder whether operation is really worth while, or whether other methods of treatment should not be tried first. In connexion with the surgery of Graves's disease another reference must be made to medical treatment. In very severe cases medical treatment, in the form of absolute rest in bed, diet, strontium bromide, Lugol's solution, etc., is most valuable as a preliminary to, and a preparation for, the operation, frequently rendering the patient fitter to stand the strain of the latter. On the other hand, in moderately severe cases, or where one sign or symptom is present to any marked degree or is progressing, medical treatment, though useful as a preparation, should not take the place of operation, for it does not lead to so marked, so permanent, or so rapid an improvement, and in such cases it should not, in my opinion, be continued for more than two or three months. If the operation is undertaken reasonably early, not only is the patient in a better condition to stand it, but a better result is likely to be obtained in the end and much time and trouble saved.

I would lay particular stress upon this question of time and trouble for the patient, for many cases of Graves's disease, by careful medical supervision and treatment by means of repeated long rests in bed, are enabled to carry on semi-invalid lives for long periods, whilst were they to undergo surgical treatment early in the complaint, their return to health would come very much sooner and be much more complete. The operation mortality has now proved to be so small that the risk may very justifiably be run in an attempt to obtain a cure for a disease of so serious a character. In this way the position of the surgical treatment of Graves's disease is not unlike the position of surgery in the treatment of gastric ulcer, for the economic and the time-saving factors must be considered in both. In mild cases there are not any actual contraindications to operation, other than independent gross constitutional disease, but there is always the question as to whether the disease is sufficiently severe to warrant exposure of the patient to the discomforts and expenses associated with an operation. In the more severe types we have before us a large number of signs and symptoms for consideration, and I do not consider that irregularity or great rapidity of the pulse, even up to 200, marked cardiac dilatation, or fibrillation necessarily contraindicate operation. Fibrillation, in particular, is often enormously improved soon after a thyroidectomy—often within two days—and fibrillating cases do so well that I would almost go so far as to say that I prefer them! Nor do diarrhoea and vomiting, marked loss of weight, or the presence of acetone in the urine, prevent operation, provided that it is done under a suitable anaesthetic, that the mental condition of the patient is moderately good, and provided still more that she is willing and anxious to have the operation done.

Nervousness and emotional instability are, of course, nearly always present, and even though these are very marked they do not constitute any bar to operation; but if mental symptoms of a maniacal, delusional, or melancholic type are setting in operation does not appear to hold out a reasonable prospect of improvement, and may, in fact, make the patient's condition worse than before.

One is occasionally asked to see, with a view to operation, patients who are, to all intents and purposes, certifiable lunatics, and who have enlarged thyroids (often with other signs pointing to Graves's disease), but, needless to say, thyroidectomy is not likely to benefit them.

Five patients of this kind, with more or less marked signs of Graves's disease, and delusions, suspicions, or melancholia, have been treated by the application of radium. Two of them are no better, one is much improved, and the other two appear at present to be quite well. It is, however, too early to feel certain that the radium is responsible for this, but it appears to be quite worth while to use it again in similar cases.

There are other associated conditions which entirely negative operation—namely, an age of over 65, the presence of diabetes or other gross constitutional disease, great fear or unwillingness to undergo operation, and the presence of oedema due to a failing heart. As is well known, the majority of sufferers from this complaint are women, and they appear to derive more benefit from the operation than do the male sufferers.

CHOICE OF ANAESTHETIC

The question as to which form of anaesthetic is preferable for these operations has recently given rise to much discussion. There is little doubt that chloroform is highly dangerous to patients suffering from thyroid toxaemia, and if a general anaesthetic is to be given at all it must consist of ether, and as little ether as possible. Given by means of the intratracheal tube, ether is convenient for both surgeon and anaesthetist in all operations about the head and neck, but in exophthalmic goitres these advantages are apparently outweighed by the facts that (1) a considerable depth of anaesthesia is required at first in order to pass the catheter into the trachea, and (2) the passage of this catheter entails a certain amount of manipulation of the neck, while the fewer manipulations there are throughout this operation the better. For these reasons ether, if used at all, is better given on an open mask. Though the milder cases can be operated upon safely under open ether, rectal ether, or gas and ether, the severe cases are subjected to a much smaller risk under local anaesthesia. Recently, in all except the very severest cases, we have been using avertin in the rectum, combined with a minimal amount of gas and oxygen, or, in the very bad cases, combined with local anaesthesia. In several hundreds of cases we have so far had no trouble at all. The dose of avertin should be slightly greater per body weight than one would give to ordinary abdominal cases. We therefore make a practice of doing a thyroidectomy on these patients under some special form of light open anaesthesia, except in the very severe cases. Here a local anaesthetic is far safer, and in some severe instances one can do the operation comparatively safely by this means when one simply would not dare to give the patient a general anaesthetic at all. This applies especially to the cases where the heart is grossly disorganized, the apex beat perhaps in the axilla, and, often, marked fibrillation present. If a local anaesthetic is being used the patient is rendered sleepy or semiconscious either by means of avertin or by a large dose of paraldehyde in the rectum, or of morphine hypodermically some few hours before. Hyoscine is best avoided. The operation of thyroidectomy, performed under local anaesthesia for an adherent and highly vascular exophthalmic goitre, is naturally somewhat of a strain for both patient and surgeon, but with a combination of coaxing and cunning it can usually be done perfectly satisfactorily. If asked whether they would prefer a local or a general anaesthetic women patients, at any rate, will often choose the local; men do not tolerate it so well.

AMOUNT OF GLAND TO BE EXCISED

Another exceedingly important consideration in connexion with these operations is the amount of gland tissue that should be removed. It cannot be too strongly emphasized that removal of one thyroid lobe (hemithyroidectomy) is hardly ever sufficient completely to cure a case of Graves's disease, and that, if a permanent cure is aimed at, it will be necessary to remove one lobe, the isthmus, and a third, or even two-thirds or more, of the opposite lobe, according to circumstances. It is usually feasible to do all this at one operation, but occasionally, where the gland is abnormally adherent (as after previous *x*-ray treatment), or where the patient is exceedingly ill—it has to be done in two separate stages, one lobe being removed at the first operation, while later on a portion of the other lobe is excised.

There is very little chance of removing too much gland, provided the patient can stand it, and I have several times removed the whole gland. But all surgeons are painfully conscious of having, on occasions, not removed enough of the gland. Removal of one lobe will always produce considerable improvement, but it is not the best that can be done, and hardly ever cures the symptoms. There have been many cases in the past in which one lobe, or even more, of the thyroid gland of an exophthalmic patient with a large goitre has been removed, and yet the patient still has left in the neck, after the operation, thyroid tissue far greater in amount than that of the normal gland. How can this possibly produce a cure? It is all-important to remove sufficient gland tissue, and provided that a piece the size perhaps of one normal thyroid lobe or even less is left in the neck one would theoretically like to remove all the rest. The practical limit to the amount that can be removed is, of course, set by how long or how severe an operation the patient's condition is equal to; for a long thyroid operation, especially if done under local anaesthesia, is undoubtedly exhausting for both patient and surgeon. Thus it is not always possible to remove quite as much thyroid tissue at a time as one would like; the necessity for a second operation may then arise.

The danger of leaving too little thyroid behind in the neck is not real, for exophthalmic thyroids are curiously apt to have outlying nodules and large lobes projecting behind the larynx on both sides, and there is probably always more thyroid tissue left *in situ* than would appear, even after extensive removal. Moreover, quite a small quantity of the gland tissue found in this disease seems to be sufficient to keep off any symptoms of myxoedema and to preserve the normal thyroid balance of the body. One cannot leave the question of extensive removal of the thyroid tissue without some reference to the parathyroid bodies and their supposed association with tetany. For many years I knew of no surgeon who had had a case of real tetany after thyroidectomy, but recently I have seen two. Nevertheless, it seems that in the performance of the operation the parathyroids may really be almost completely ignored.

DETAILS OF OPERATIVE TECHNIQUE

It is the practice of some surgeons, when performing thyroidectomy, to leave *in situ* shavings of the posterior surface of the gland in the neighbourhood of the inferior thyroid artery, with a view to protecting the recurrent laryngeal nerve; but this should not be done—at any rate when dealing with cases of Graves's disease—for these small portions of gland tissue are capable of undergoing, and do undergo, growth and hypertrophy, and later may increase to such a size that their internal secretion is sufficient to cause a recrudescence of the symptoms and a failure of the operation. It is therefore of the greatest importance that the gland should be cleanly dissected out and no outlying shavings left behind. This applies equally to that stage of the operation when the superior thyroid artery is being tied and cut; this must be done cleanly above the gland, and portions of thyroid tissue should not be left on the stump of the artery, though it is tempting to leave them when the superior thyroid pole lies high up in the neck and is difficult to reach. The retrolaryngeal lobe should also be removed, at least on one side.

The recurrent laryngeal nerve, which divides up into branches some little distance away from the larynx, is at times very closely incorporated with the gland substance, and damage to this nerve may be a most serious accident for the patient. Apart from being cut or tied in a ligature—which should never occur—the nerve is remarkably sensitive to handling, pinching, bruising, or stretching, and minor insults which would have no effect on most of the nerves in the body may be sufficient to put this nerve or its abductor fibres out of action for many weeks. It should not be in danger if the wound is kept dry and

the dissection is carried out with a blunt instrument kept close to the gland substance. The gland is usually tightly adherent to the trachea at one point in front, and though a blunt instrument has been used to separate it at the sides, the scissors will nearly always be necessary to effect the separation from the front and central portion of the trachea. There is no need to lay stress on the special difficulties of this operation—the true exophthalmic gland has outlying lobes and nodules, and is very hard, exceedingly vascular, friable, and adherent. This may render very difficult the process of dislocating the lobe and lifting it up to separate it from the trachea, while the patients, if the disease is at all advanced, stand loss of blood very badly, and every effort must be made to diminish haemorrhage. The veins are usually more troublesome than the arteries—as in all branches of surgery—and though a local anaesthetic has the effect of making the superficial tissues avascular, it has no such effect on the deeper ones. Further, the fact that the patient is not unconscious makes a haemorrhage, should it occur, more difficult to deal with.

The mortality of this operation in the last 900 cases has been 2½ per cent.

RESULTS OF TREATMENT

It may well be asked, "What are we to expect from this operation in the way of improvement?" and the first question that the patient will ask is probably about the mortality. A mortality of 2½ per cent. is not unduly high when one is dealing with so serious a complaint. This disease leads inevitably to prolonged and often very serious ill-health, and gives rise to symptoms which are most unpleasant to the patient and even to her friends—especially the incessant palpitation and rapid action of the heart, the nervousness, jumpiness, and the sleeplessness. Moreover, in many cases—especially in women over 40—it leads to gross disorganization of the heart and to death. It is without doubt justifiable to run a small amount of risk in an attempt to effect a cure. Nevertheless, one cannot help regarding all patients with a certain amount of anxiety for the first two or three days after operation.

Of the twenty-two patients in this series who succumbed eight died of pneumonia within the first four days, and the other fourteen within sixty hours of the operation with the symptoms of what one is accustomed to call acute hyperthyroidism. After three or four days, therefore, any danger of death would seem to be over. Following the operation there usually appears to be an improvement, which is more marked and rapid in the subjective symptoms than in the physical signs, and patients often look and feel much better within a few days of the thyroidectomy. It is often not for a month or so that really marked improvement in the physical signs sets in. This improvement in subjective symptoms often disappears after a few weeks, when the patient goes back to her own home, but reappears later as a permanency in two or three months, and is then accompanied by marked improvement in the physical signs. A long rest for some months after the operation is absolutely essential.

As a rule, after three or four months we find that patients who have had an adequate amount of thyroid gland tissue removed feel well, eat well, sleep well, and can do their day's work, though I do not think it wise for them to recommence their normal life quite as soon as this. Though they look and feel well and put on weight, it is frequently found on examination that the pulse rate, while very much slower than it used to be, has not quite come down to the normal, remaining between 80 and 90, and that the cardiac dilatation, though considerably less, has not quite gone. Irregularity of the pulse, acetonuria, and diarrhoea, if previously present, almost invariably disappear, and the nervous excitability, tremor, and jumpiness are greatly improved; but the exophthalmos, though much less marked than before operation, rarely if ever vanishes completely. Those patients who receive surgical treatment for the condition comparatively early in its course—that is, before they have developed the gross degenerative conditions of the myocardium and of other viscera that set in sooner or later—should all, if a sufficient amount of thyroid tissue is removed, become well in the sense that they should be able to lead a normal life, do their ordinary work, and sleep the sleep of the just. On the other hand, it is no use pretending that operation on a case with a grossly dilated and fibrillating heart and advanced myocardial degeneration will ever make that heart perfect again, although it will make it very much better. Palpitation and shortness of breath—two symptoms especially unpleasant to the patient—usually show the greatest amount of improvement.

As regards the effect of the operation on the loss of weight, which is often so serious a feature in a bad case, the gain in weight following operation is nearly always marked, and may even become embarrassing. Another very satisfactory feature about this branch of surgery is that, as a general rule, the bad cases appear to derive more improvement from, and to be even more pleased with the results of, the operation than do the slighter cases.

As in other diseases, it is difficult to compare and contrast the results of treatment by merely observing symptoms and physical signs, and it is therefore satisfactory to find that there appears to be a method by which one can attempt to measure what we may call the "physiological fitness" of these patients before and after operation. Many of these patients have had their basal metabolic rates estimated before and after operation; before operation they are nearly always 40 to 80 per cent. above that of the normal individual—this presumably representing increased tissue metabolism as a result of the hyperactivity of the thyroid. After the operation these rates fall, within a few weeks, to amounts varying from normal to + 25 per cent. above normal, and this appears to be a fixed method of estimating the "physiological improvement." There have so far been only two or three cases in which, after operation, this basal metabolic rate has fallen slightly below normal, to amounts varying between − 5 and − 10 per cent., and these patients have not, up to the present, shown any signs clinically of hypothyroidism.

Of the success of surgery in suitable cases of Graves's disease there is, I think, no doubt, but one cannot help feeling conscious that in removing thyroid tissue one is really treating symptoms and not causes, and that the primary cause is something further back and not yet removable.

THREE RECENT CASES OF ENCEPHALITIS LETHARGICA

BY

PHILIP FRAZER, M.B.

HOUSE-PHYSICIAN, GENERAL HOSPITAL, BIRMINGHAM

Introductory Note by

A. STANLEY BARNES, M.D., F.R.C.P.

Senior Physician, General Hospital, Birmingham

During the last three years a comparatively small number of cases of encephalitis lethargica have been notified. Considerable doubt has existed in the minds of many as to how far these notified cases are really encephalitis, seeing that the difficulty of diagnosis is unusual in this disease. In the last few months there have been admitted under my care at the General Hospital, Birmingham, three cases of a somewhat fulminating character in which a post-mortem examination has permitted confirmation of the diagnosis. The type of disease in these cases resembles to some extent that which was seen in the very early stages of the epidemic in 1918. Very few of such cases have been seen in the Midlands during the last few years. It is of interest to note the existence of this severe type of case during this year, as it is possible this means that a further visitation of encephalitis in epidemic form

may be imminent; it is equally possible that these are just stray cases which indicate that the epidemic has spent its force, and that in future we shall see only occasional cases appearing in sporadic form.

CASE I

A road foreman, a previously healthy man, aged 57, was admitted to the General Hospital, Birmingham, on May 30th, 1932, complaining of headache, giddiness, and double vision, with some numbness of the hands, for fourteen days. The illness began while he was at work, with sudden inability to see more than a few yards, and on reaching home he found he was seeing double. After two days' rest in bed the double vision disappeared. On admission he complained of a dull, heavy sensation in his head, and a feeling of giddiness and insecurity when on his feet. He had had some nausea, but no vomiting. Sleep was good.

Examination.—The patient was found to be a well-nourished man; he gave an intelligent history, but his speech was slow and indistinct. Bilateral ptosis and right facial weakness were apparent as he lay in bed. The pupils reacted to light, but not to accommodation. Both fundi were normal. Both internal rectus oculi muscles were paralysed, and irregular nystagmus was present on looking upwards and downwards. There was slight weakness of the muscles of mastication on the right side and a definite right facial weakness. The other cranial nerves were unaffected. There were no other motor or sensory changes present. The other systems were normal. Lumbar puncture three days after admission revealed a clear, colourless fluid, not under pressure: cells, less than 1.5 per c.mm.; sugar, 68 mg. per 100 c.cm.; protein, 85 mg. per 100 c.cm. (globulin negative); chlorides, 730 mg. per 100 c.cm.; Lange curve, 1233210000; Wassermann reaction, negative.

Progress.—On June 8th the patient became irrational, and from this time drowsiness and lethargy became a prominent feature of the disease. On June 10th the patient was able to swallow only with difficulty, and articulation was very indistinct. By this time a complete ophthalmoplegia had developed—the eyes looking straight forward—but the pupils still reacted to light. The drowsiness had now become constant. Shortly after this, paralysis of the muscles of deglutition supervened, and nasal feeding was resorted to. On June 16th the patient was comatose, with Cheyne-Stokes respiration. All four limbs were slightly rigid, the abdominal reflexes were absent, the tendon-jerks exaggerated, and both plantar responses extensor. There was incontinence of urine and faeces. Though previously afebrile he now began to run a temperature varying between 101° and 102°. He remained in this condition until he died, four days later.

Post-mortem.—The brain surface was moist, the dura mater was not adherent, and there was no flattening of the convolutions. A horizontal section across the cerebral hemispheres revealed no macroscopical abnormality, but the brain stem and basal ganglia showed multiple small haemorrhagic spots, which were particularly obvious in the grey matter surrounding the Sylvian aqueduct and in the floor of the fourth ventricle. The appearances were typical of encephalitis lethargica. The lungs showed an early hypostatic pneumonia; the other organs were normal. Microscopical sections taken from the region of the basal ganglia, the mid-brain, pons, and medulla also showed the appearances expected in this condition—namely, large collections of lymphocytes in the perivascular spaces of the smaller vessels. There was also degeneration of the ganglion cells in several areas.

CASE II

A married woman, aged 52, was admitted to hospital on August 8th, 1932, after a fortnight's illness. The initial symptoms were of feeling tired and weak, with rapid pulse and an occasional rise in temperature. A few days before admission she became delirious. No physical signs were discovered at any time by her doctor.

Examination and Progress.—The patient was delirious and very restless; temperature 99°, pulse 110, respirations 27. A complete neurological examination was out of the question owing to the extreme restlessness and irritability of the patient, but as far as could be made out there was no paralysis of the cranial nerves, trunk, or limbs. The other systems were normal. Lumbar puncture was performed under light ether anaesthesia. The fluid obtained was clear, colourless, under a tension of 235 mm. of water, and contained no organisms. The cell content was less than 1 per c.mm.; sugar, 57 mg. per 100 c.cm.; protein, 70 mg. per 100 c.cm.; chlorides, 745 mg. per 100 c.cm.; urea 111 mg. per 100 c.cm.; Wassermann reaction, negative. There was no return of consciousness following the anaesthetic, and the patient died ten hours later with pin-point pupils, a temperature of 107°, pulse of 160, and respiration of 60.

Post-mortem.—The whole of the grey matter exhibited a slightly pink colour; this was particularly noticeable in the tissues of the basal ganglia and in those of the brain stem, where the brain substance was also unusually soft. The grey matter around the Sylvian aqueduct and the floor of the fourth ventricle showed minute haemorrhagic spots, and larger haemorrhages were to be seen in the fillet and elsewhere in the brain stem. Sections taken from the mid-brain, pons, and medulla for microscopy showed local areas of oedema and softening of the brain substance with vascular congestion. No perivascular "cuffing" by lymphocytic infiltration was seen. Considerable neuronic degeneration was present.

CASE III

A married woman, aged 39, was admitted to hospital on September 5th, 1932, after one week's illness, consisting of headache, loss of appetite, and constipation. Two days before admission she became delirious, and then completely negative mentally.

Examination and Progress.—The patient was a well-nourished woman; she was lying very still in bed and occasionally moving her head from one side to the other. There was rhythmic blinking of the eyelids, which persisted the whole time until the patient died. The jaws were tightly clenched and swallowing movements were entirely absent, the saliva dribbling from the patient's mouth. A certain amount of head retraction was present, and the arms were flexed at the elbows and rigid. The patient would not obey any command, and did not react to painful stimuli. Indeed, lumbar puncture performed without a local anaesthetic evoked only a slight flinching movement. The temperature was 103°, pulse 90, and respirations 25. Both fundi oculi were normal; there was no ophthalmoplegia or facial weakness. There was a certain amount of rigidity present in the arms—chiefly in the flexor muscles—which diminished on manipulation. The arm-jerks were brisk; the abdominal reflexes, both superficial and deep, were absent; the legs were slightly rigid with diminished reflexes, and the plantar responses were flexor. There was complete incontinence of urine and faeces. The other systems were normal. Lumbar puncture was performed on the following day, and 6 c.cm. of faintly blood-stained fluid were removed. The analysis was as follows: cells, mostly polymorphs, 70 per c.mm., a little blood present; no T.B. or other organisms seen. The supernatant fluid of the centrifugalized specimen contained: sugar, 96 mg. per 100 c.cm.; protein, 170 mg. per 100 c.cm. (globulin positive); chlorides, 722 mg. per 100 c.cm. The patient's mental condition remained the same throughout; she uttered no sound, but made snarling and twitching movements with her lips. Rhythmic movements of the eyes persisted, and dissociated movements of the eyes themselves soon appeared. Nasal feeding was resorted to as the patient was unable or refused to swallow. The patient died on September 8th—that is, three days after admission—the temperature rising to 108°.

Post-mortem.—On removing the skull vault and dura mater the brain convolutions showed extreme congestion without any flattening, oedema, or exudate. Examination of the cerebral cortex, basal ganglia, mid-brain, pons, and medulla revealed great congestion, the grey matter showing a distinct pink coloration. In the anterior part of the corpus callosum, close to the anterior pillars of the fornix, there was a well-defined small haemorrhage; this was more than a petechial haemorrhage. Throughout the grey matter of the brain stem there were innumerable tiny points of haemorrhage; they were particularly well marked in the grey matter around the Sylvian aqueduct and in the floor of the fourth ventricle.

In the heart there was an area of recent haemorrhage under the endocardium of the septal wall of the left ventricle and many subpericardial petechiae. The lungs were very congested; both the lower lobes were partially consolidated by very definite areas of bronchopneumonia. There were also

many small subpleural haemorrhages. The other organs were normal. Microscopically the appearances were characteristic of encephalitis lethargica. The sections of the mid-brain, pons, and medulla showed the following features: great congestion of all the vessels with infiltration of the perivascular spaces, which were also dilated. This perivascular cuffing was most marked in the sections from the pons and medulla. Haemorrhages were seen in various parts, a very large one being present near the lamina terminalis. The ganglion cells in the brain stem showed all degrees of degeneration—some of it pigmentary—and loss of nuclear staining.

COMMENTARY

Three cases of encephalitis lethargica, proved at post-mortem, are described. In all of them there was a prodromal period lasting from one to two weeks, consisting of malaise, headache, lethargy, and constipation.

The first case pursued the characteristic course of a subacute disease, with its maximal incidence on the mid-brain, spreading thence upwards to the hypothalamic region and basal ganglia, and downwards to the pons and medulla oblongata.

Cases II and III were similar to one another in type. Both were remarkable for the fulminating course of the disease once the prodromal period was passed, the acute stage lasting only four days or so. Both showed a complete mental obliteration, and both terminated similarly with a hyperpyrexia.

The macroscopic post-mortem findings were typical of encephalitis lethargica, the main points being the pink discoloration of the grey matter, the vascular congestion, and the presence of multiple minute haemorrhages, giving the brain a flea-bitten appearance. This was especially noticeable in the region of the basal ganglia and in the brain stem. The exceptional severity of the disease in Case III was attested by the presence of haemorrhages beneath the endocardium, pericardium, and pleura—a finding to be expected where an acute toxic process has been at work.

Microscopically the characteristic cuff of lymphocytic infiltration in the perivascular spaces was present in two of the cases. At the same time there was degeneration, often pigmentary in nature, of the nerve cells. The sections also showed a certain amount of spreading apart of the neuroglial elements due to oedema. Although the sections of Case II did not show the lymphocytic cuffing of the small vessels, neuronic degeneration was a marked feature, and the similarity of the clinical course of the disease to that of Case III, taken in conjunction with the macroscopic appearance of the brain, leaves little room for doubt as to the true nature of the condition.

I wish to thank Dr. Stanley Barnes and Dr. A. Brian Taylor for their assistance and advice in the writing of this paper, and Dr. F. W. Mason Lamb, pathologist to the General Hospital, Birmingham, who performed the necropsies and reported on the histological sections.

PAIN REFERRED TO THE EAR*

BY

E. WATSON-WILLIAMS, *M.C.*, CH.M., F.R.C.S.ED.

SURGEON IN CHARGE, EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY; LARYNGOLOGIST, BRISTOL AND SOUTH-WESTERN RADIUM CENTRE

Pain felt in an otherwise apparently normal ear presents a diagnostic problem often of some interest. I say "apparently normal" since at times the membrane shows no appreciable change, even when mastoid suppuration or yet more serious trouble is present.[5,6] But when the earache is really due to disease elsewhere, if on examining the ear we find some lesion possibly sufficient to account for the pain it is only too easy to walk into the trap—particularly where the pain is severe or the patient manifestly ill and we feel compelled to adopt active measures without delay. The pain may be due to trouble near but not in the ear, such as arthritis of the temporo-mandibular joint. Earache is not infrequently the first symptom of mumps, and may occur before any swelling is noticed. Even a mixed tumour of the parotid may have earache as the only symptom.

HERPES OTICUS

Herpes oticus provides another possible catch. The pain is intense, sometimes with great tenderness of the meatus and mastoid, and may precede the eruption by several days—among ten cases I found intervals of six, four, and three days. There is some fever; in one case the temperature was 102° F. Deafness, nausea, and slight vertigo are common, and the membrane may be a trifle pink. Points of diagnostic importance are a constant boring ache—as contrasted with the fluctuating, throbbing pain of otitis—and extreme tenderness of the skin to very light touch. Even when a vesicle simulates a perforation, careful examination will reveal the difference, the discharge being slight and sanious; sometimes a history of exposure to varicella is obtained. No doubt the majority of cases of herpes oticus are due to involvement of the geniculate ganglion,[2] though in my experience only one-third have facial paresis, and I have only once seen vesicles on the tongue. Twice I have seen an eruption on the soft palate, with dysphagia, which is perhaps evidence of glosso-pharyngeal affection. Herpes oticus with paralysis of the vocal cord has been recorded.[3] The two following cases illustrate vagus herpetic earache, and the third case vagus referred earache without herpes.

CASE I.—*Earache from Herpes Oticus, with Pneumonia*

W. H., aged 14, had severe pain in the left ear for three days, following a cold. He had become much worse, with giddiness, vomiting, and a temperature of 104.4° F. and pulse of 120. There was slight sanious oral discharge and extreme tenderness of the mastoid tip. I was sent for late at night to perform an operation. When I saw the boy in the anaesthetic room I was struck by the "pneumonia" look—flushed cheeks, hot dry skin, bright eye, etc. The ear showed what looked like a perforation just in front of the umbo, but on careful inspection I thought it was a ruptured vesicle. All that could be found in the chest were a few crepitations in the right base, but thirty-six hours later (not before) there were typical signs of lobar pneumonia.

CASE II.—*Earache from Herpes Oticus, with Pneumonia*

J. E. T., a man aged 31, had symptoms of fever, deafness, and right earache, worse on coughing, following influenza. He had typical pneumonia of the right upper lobe, and a herpetic eruption on the right tympanic membrane.

CASE III.—*Earache due to Pneumonia*

A boy of 10 came to the casualty department of the Royal Infirmary complaining of bad earache of a few hours' duration, following a "chill." There was no tenderness, and the ear appeared quite normal; but the boy was obviously ill, and examination of the chest showed consolidation of the left lower lobe.

OTHER CAUSES

Neuritis is a not uncommon cause of earache. Exposure to cold is the usual aetiological factor, and there is sometimes facial paralysis in addition. I have seen a number of cases in taxi and lorry drivers, generally on the right side—probably because that ear is more exposed to the wind than the other. The trouble is usually transient, but some cases have proved very persistent. The pain of neuralgia is seldom confined to the ear; indeed, it tends as a rule to be felt round rather than in it. True geniculate tic douloureux seems to be very rare; the pain is paroxysmal, confined to the ear, severe and lancinating in character.[1]

* Opening paper to discussion on referred pain, at a meeting of the Sections of Otology and Laryngology of the Royal Society of Medicine, held at Portsmouth, June, 1932.

When no local explanation of the pain is found, attention is, of course, directed to the mouth, pharynx, larynx, and nose. Dental disease is, in my experience, much the most common cause of "referred" earache. Any tooth may be responsible, but nearly always it is a molar. Even when the teeth appear quite sound, a meticulous examination by a dental surgeon may bring to light unsuspected caries, or a skiagram may show an impacted wisdom tooth. I have been puzzled by a case of earache in a child of 3. Twice, after a cold, there was intense earache all night. The membrane was normal, warm glycerin drops did not relieve, adenoids were absent, and the teeth appeared to be healthy. The dental surgeon, however, found an area of caries, and removal of the offending tooth banished the trouble.

Such conditions as a foreign body in the pharynx, a quinsy, laryngeal tuberculosis, or a nasopharyngeal fibroma may produce earache; but it is not likely to be the first or the most prominent symptom. It may be, however, in the case of a tonsil calculus or a crypt infection. Ulceration, due to Vincent's spirillum concealed behind the faucial pillar, may occasion difficulty. Cancer in any part of the nasopharynx, pharynx, larynx, or tongue frequently gives rise to pain in the ear, especially when the tonsil or the pyriform fossa is involved. Such pain, worse at night but not related to swallowing, may precede other symptoms by several weeks. Abernethy observed: "Wool in the ear and a lump in the neck mean cancer." The point is important, since many of these patients have very evil teeth, and only too often, even where manifestly malignant glands are present, time is wasted in awaiting the results of dental treatment. When the primary growth is in the nasopharynx or the auditory tube, otitis media is an early and often misleading complication.

AFFECTIONS OF THE SINUSES

Nasal sinusitis may provide a most elaborate trap for the surgeon—especially sphenoidal sinusitis, which (particularly in the young) is easily overlooked. It arises often as a complication of influenza: the pain is severe, and accompanied by fever and other evidence of suppuration; the severity of the symptoms may actually be due to the *absence* of discharge from the affected cell. Sometimes the ear itself is infected. Difficulty with regard to the other sinuses arises only rarely. In my experience the pain of chronic sphenoidal sinusitis is typically felt somewhat behind the mastoid; but in acute sinusitis the pain is actually in the ear, as pointed out by Mr. Tilley in 1905.[4] A vertico-submental skiagram is of great value in diagnosis.

CASE IV.—*Earache due to Antral Suppuration*

D. G., aged 10, complained of left earache during four days, following a cold. The pain was throbbing in character, and worse at night. The mastoid was slightly tender. Temperature 100.6° F., pulse 80. Ears and nose showed nothing abnormal at all; there were no adenoids, but the tonsils were enlarged. Four days later the temperature was still high; earache persisted; there was vomiting and giddiness—no nystagmus; hearing normal; nose normal. The attack subsided, and he went home. A week later muco-pus was seen in the left middle meatus. Exactly a month after the first complaint I explored the left antrum. It was full of thick pus, and was opened; the right antrum contained clear mucus; there was a complete recovery, with no further attacks.

CASE V.—*Acute Sphenoidal Sinusitis simulating Mastoiditis*

T. G., aged 15, was brought to me in January, 1930, as a case of acute left mastoiditis. Early in 1926 he had had pneumonia with empyema, since when the left ear had discharged. Six weeks after an operation for tonsils and adenoids in December, 1929, he complained of pain behind the left ear, with tenderness. The temperature was 101° F. He was considered in the out-patient department to be suffering from mastoiditis. I was operating at the time, and regret that I did not myself examine him. There was no post-aural oedema, and a Schwartze operation revealed perfectly normal bone. The cells contained air and a trace only of moisture, the antrum was empty and healthy, and only a trace of pus came back through the aditus when it was cleared. It seemed impossible that this would account for his symptoms. I therefore passed a cannula into the left sphenoidal sinus, and drew up several cubic centimetres of thick pus. The right sinus was healthy; both antra were infected, the pus being streptococcal. Chips from the mastoid were sterile. The left sphenoidal sinus was opened. He made a good recovery.

CASE VI.—*Sphenoidal Sinusitis, Meningitis, Septicaemia: Death*

E. E., a boy aged 9, previously healthy, had fourteen days' fever and malaise, seven days' headache and right earache; vomiting, collapse. On admission, obvious meningitis. Lumbar puncture—fluid turbid, streptococcal. Two c.cm. of thick pus aspirated from right sphenoidal sinus. Death occurred two days later. Necropsy revealed purulent meningitis; the right sphenoidal sinus was full of pus, and there were vegetations on the mitral valve.

CASE VII.—*Recurrent Sphenoidal Sinusitis simulating Mastoiditis*

R. A., aged 4, complained of "attacks" during which he suffered intense headache, with fever, and "lost control of himself; he would beat his head on the floor with the pain." In September, 1930, he had measles, and came to me a month later with right suppurative otitis media (first attack). The nose was running; he was drowsy and irritable, and was vomiting—temperature 102.8° F. There was no nystagmus or rigidity of neck, nor was there any additional evidence of mastoiditis. I advised against operation. The aural discharge ceased and the hearing became normal, but pain in the ear persisted. He had another exactly similar attack in December. In January I explored the antra, a skiagram having shown the right one to be opaque. Both were healthy and sterile. A week after this he had a similar attack, with earache but no other sign of otitis. During the year he had several more attacks, in one of which there was right frontal headache and nasal discharge. In January, 1932, I again explored the sinuses. The antra were quite healthy, as was the left sphenoidal sinus. The right sphenoidal sinus was full of thick streptococcal pus, and was opened. He has since been free of his trouble.

This child had precocious development of the frontal sinuses, but on account of his age I fear I neglected the possibility of sphenoidal sinusitis when I first saw him.

OTHER POSSIBILITIES

Earache may be the first symptom, and the only "localizing sign," of meningitis of any type—tuberculous, meningococcal, pneumococcal, or septic. In the latter particularly it is intense and persistent, and is not relieved by rupture or incision of the membrane. Any of these varieties of meningitis may occur either with a normal membrane or with otorrhoea.[5] Pain referred to the ear from some other intracranial lesion may lead one astray.

CASE VIII.—*Earache due to Aneurysm of the Circle of Willis*

R. R., aged 40, had had very bad pain in the left mastoid area for ten months. For six months the vision of the left eye had been getting misty, and now the left visual field was reduced to a 10-degree circle. The ear was quite normal. A skiagram showed that the right sphenoidal sinus was less clear than the left. Exploration of the sinuses was negative, except that from the right sphenoidal a little sterile muco-pus was drawn, from the left sphenoidal streptococcal muco-pus, and from the left posterior ethmoidal cell pus which grew pneumo-bacilli; the two latter were opened. Six days after the operation he developed signs of meningitis, to my horror; on the ninth day his temperature came down, but he suddenly collapsed, with extreme cyanosis of the left side of the head and neck, and died immediately. At post-

we found a leaking aneurysm of the left side of the circle of Willis, which had burst.

In another case in my department, under Mr. Angell James, mastoiditis was simulated and an operation performed; the lesion was an aneurysm of the basilar artery.

Oöphoritis appears occasionally to produce earache. Sometimes we are compelled to regard the earache as functional in origin, as in the case described below.

CASE IX.—*Neurotic "Earache"*

R. N., a female aged 24, was admitted as a case of mastoiditis, with severe left earache, intense tenderness to lightest touch on mastoid and behind, giddiness, and falling. No nystagmus or nausea. Temperature 98.6° F., pulse 76; hearing normal, tympanic membrane normal. She seemed quite quiet and intelligent, and anxious to have an operation —"anything to get rid of the pain." Careful examination revealed no physical signs. I made the diagnosis of quasi-hysterical neurosis, which rather startled her own doctor. When told that no operation was necessary she lost all pain. Later I found out that she had just lost her job. Three years before she had suffered from hysteria, her betrothed having married her best friend just before the date fixed for her own wedding.

THE LATENT MASTOID AS A CAUSE OF CHRONIC AURAL SEPSIS

BY

GILBERT CHUBB, D.Sc., F.R.C.S.

SURGEON IN CHARGE OF THE EAR AND THROAT DEPARTMENT, WESTMINSTER HOSPITAL

In the vast majority of cases of acute otitis media the path of infection is via the Eustachian tube. Owing to the early closure of the latter, the inflammatory exudate is under pressure. It must be rare indeed for the mastoid antrum to escape infection.

The acute mastoiditis which occasionally supervenes may present the classical signs of mastoid involvement. Often, however, these are conspicuous by their absence. The only definite physical sign may be the persistence of the meatal discharge. Reluctantly we operate, and we find a frankly purulent mastoid. Many such cases must be missed. What becomes of them? The answer is given by the chronic discharging ears that come to the radical mastoid operation. Whatever may be the condition determining operation in these latter cases, however completely mastoid signs and symptoms may be absent, they almost all agree in presenting at the operation unequivocal indications of old-standing mastoid infection.

When we consider the occasional, almost fortuitous, discovery of the more or less latent mastoid infection in the recent case, and the almost constant indications of prolonged latency of the mastoid infection in the old-standing case, is not the conclusion inevitable that these latter represent the mastoid extension of the original acute infection which, having run throughout a latent course, has been missed? If this is so, if these latent mastoid infections remain after the subsidence of the acute otitis media, then our failure to diagnose them is responsible for the great bulk of chronic aural sepsis, with its progressive deafness and potential dangers.

How far the mastoid bone with its diploic tissue or air cells is involved will depend on the virulence of the infection, and on the resisting power of the patient. It will, however, depend also on the rapidity with which drainage is established. Rupture or paracentesis of the drum is at the best imperfect drainage for the antrum. With partial obstruction of the aditus it becomes still less efficient. With actual involvement of the mastoid bone this drainage can do little more than serve to maintain the latency of the mastoid infection.

The discharge of chronic aural sepsis may show prolonged periods of complete remission. A scarred drum alone remains to tell the tale of previous active sepsis. As there is no reasonable ground for denying this complete latency in the case of the mastoid infection, while admitting it, as we must, in the case of the tympanic cavity, we are driven to the conclusion that even the absence of a discharge is no certain ground for assuming a non-infected mastoid. Indeed, we have only to postulate the early and complete closure of the aditus to envisage the possibility of a chronic but entirely latent mastoid infection, coexisting side by side with a normal middle ear, normal drum, and normal hearing. The two following cases suggest that this actually occurs:

CASE I

A boy of about 12 was sent in with pain, tenderness, and marked swelling over the right mastoid, with a corresponding displacement of the pinna. The drum and external meatus were, however, absolutely normal. So also was the hearing. There was nothing on the scalp, and no concurrent disease to suggest a blood-borne infection. Operation disclosed a mastoid filled with pus.

CASE II

A woman of about 40 came to me with pain in the right ear of recent onset. There was no previous history of ear trouble. She had a red and bulging, but otherwise normal, drum, which I incised. Some fourteen days later there were signs of mastoid involvement. At the operation the mastoid presented every appearance of an infection of many years' standing.

Neither of these cases definitely proves that the mastoid infection originated in an acute otitis media, which, as far as the middle ear was concerned, cleared up completely. Blood-borne infections of the mastoid are, however, so rare and infections via the Eustachian tube so common that this explanation is at least a probability.

These cases must be rare, and would, in any case, be difficult to diagnose till physical signs arose. Cases in which a discharge persists after the acute stage has subsided are very much more common. They represent nearly all cases of chronic suppurative otitis media. In how many of these is the persistence of the discharge due to the presence of residual mastoid sepsis—sepsis latent save for the discharge? My experience suggests that it is in a very large proportion of them. The following cases lend support to that view:

CASE III

A girl of 12, with a copious discharge from both ears, dating from an attack of measles eighteen months previously, developed a swinging temperature. As nothing could be found to account for this, I was called in because of the aural discharge. By that time the temperature had been swinging for eleven days. A bilateral cortical operation showed both mastoids full of pus and the left lateral sinus exposed in the abscess. She recovered.

CASE IV

Another child, of about the same age, came to the out-patient department with a history of a discharging ear and some very doubtful signs of mastoid involvement. She reappeared a week later, desperately ill, with marked adenitis round the right jugular and a swinging temperature. Immediate operation on the mastoid and thrombosed lateral sinus failed to save her, and she died of meningitis.

CASE V

In pleasant contrast to the two preceding cases this boy of 16 was sent in on the strength of one sharp rise of temperature the same day. He had a small perforation in the left drum and a history of intermittent discharge from that ear. There was no tenderness or other sign of mastoid involvement. Immediate operation disclosed a septic mastoid, with pus and granulations on the exposed lateral sinus. He recovered.

Such cases could be multiplied indefinitely. They carry a twofold and very obvious lesson—namely, that a suppurating mastoid can run a completely latent course save for the ear discharge, and that when complications arise they may do so without any warning from the mastoid.

CASE VI

A boy of 10 was sent to me from the ophthalmic department with the urgent request that any focal sepsis should be discovered and eliminated. All that I could find was a small perforation in the left drum and a history of discharge. There was no tenderness, no pain, and no discharge when I saw him. In view of the urgency of the eye condition I opened the mastoid. It was full of pus.

CASE VII

A man of 20 came under my care with bilateral acute otitis media. A paracentesis of both drums resulted in his temperature becoming normal. Pain disappeared, and the left ear recovered without further intervention. The right ear on the tenth day still showed a pulsating discharge in the tympanic perforation. There was no pain, very doubtful tenderness, and the temperature was normal. Operation disclosed a frankly purulent mastoid.

CASE VIII

A girl of 6 had had pain in the left ear for some days. There was a slight temperature and some discharge from this ear. The meatus was narrowed, and there was some excoriation of its external opening. There was no tenderness. There was a history of acute earache some years previously, followed by paracentesis, but whether of one or both ears was not known. There had, however, been pain each winter, sometimes in one ear, sometimes in the other. There were no physical signs referable to the right ear at the time of examination. Both mastoids contained pus, that in the left being under pressure.

CASE IX

A girl of 8, sister of the previous case and seen a few weeks later. She had had pain in the left ear for three days. There was no temperature, no tenderness, and she was cutting a tooth on that side. The tonsils and adenoids had been removed five years previously. Two years ago there had been earache, both sides (?). There was no history of any discharge. In the left ear there was an accumulation of epithelial debris and, in the antero-inferior quadrant, a puckered area and some granulation tissue (?) suggesting a partially closed perforation. A similar area, but without granulations, was observed in the same position on the right drum, which was thickened. Shrapnell's membrane on the right side was red, but not bulging, and there was no tenderness; there was slight deafness. On the following day there was slight tenderness over the tip of the left mastoid, none over the right. Temperature still normal. Both mastoids were filled with granulation tissue and pus.

In both these children (Cases VIII and IX) the ears recovered completely, and even a long spell of whooping-cough the same winter failed to produce aural symptoms.

CASE X

A boy of 12. A recent attack of acute tonsilitis had resulted in an exacerbation of a bilateral ear discharge, which had been intermittent since acute earache following measles two years previously. The temperature was raised, and there was definite tenderness over the right mastoid. There were no physical signs referable to the left ear other than the discharge. At the operation there was nothing to choose between the two mastoids, both being frankly purulent.

CASE XI

A hospital nurse was warded for an attack of (?) influenza. There was a slight initial rise of temperature, which quickly subsided. Ten days later, while still in bed, she had an acute otitis media on the right side. Rupture of the drum resulted in the temperature again becoming normal, and it remained so. Nevertheless, three weeks later, the discharge, which in the meantime had steadily diminished in quantity, could still be seen pulsating at the perforation. There were also vague pains referred to that side of the head. There was no tenderness, and *x* rays failed to show any difference between the two mastoids. At the operation there was a considerable quantity of pus under pressure, and a very forwardly placed lateral sinus was already exposed to the sepsis. The organism was *Streptococcus haemolyticus*.

These cases are not exceptional. On the contrary, they represent my general experience. They must represent the experience of many others also. Whether or no latent mastoid sepsis is really as often the cause of chronic aural sepsis as these cases would suggest should be speedily settled once we are alive to its possibility. In all the cases in which I have performed the cortical mastoid operation solely on account of the persistent discharge there have been only two in which the mastoid was not frankly purulent. It cannot, however, be supposed that every case of persistent discharge following an acute otitis media is due to the presence of mastoid sepsis. At present every such case must be considered on its merits. I would suggest that in doing so the probable frequency of unsuspected mastoid sepsis should be borne in mind.

THE TREATMENT OF CHRONIC AURAL SUPPURATION WITH IODINE POWDER

BY

R. SCOTT STEVENSON, M.D., F.R.C.S.ED.

SURGEON TO THE METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL

The purpose of this short article is to emphasize the value of a simple method of treating chronic middle ear suppuration by insufflation of so-called iodine powder, which consists of iodine 0.75 per cent. in boric acid powder. Although I began to use this powder tentatively and without much conviction of its value two years ago, I now use it as a routine for every case of chronic middle ear suppuration, first mopping or sucking out the discharge and then blowing the powder through the perforation into the middle ear and until the deepest part of the meatus is full. Nascent iodine apparently gets into the furthest corners of the affected middle ear. A simple powder blower with a glass or wooden stem and a rubber bulb is quite adequate for the patient's own use, but a special all-glass or vulcanite powder insufflator should be used by the practitioner.

I first came across this method of treatment in Chicago and New York in the autumn of 1930. The iodine powder used was an American proprietary preparation, originated by Nathan Sulzberger, a New York chemist, about 1915, and was called by him "iodosan." It was used first of all for suppurative conditions of the nasal cavities, and only afterwards for chronic middle ear suppuration. The percentage of iodine in the powder varied from 10 to 0.75, but it was found more effective and much less irritating in the smaller percentages; in America it is now used commonly as 0.75 per cent. for the initial treatments and as 2 per cent. after a number of treatments have been given.

Many practitioners are under the impression that the treatment of ear discharge by powder insufflations is dangerous, as hard concretions may form from the powder and the drainage become obstructed, especially with small

perforations in the attic region. This fear is groundless, because the iodine and boric powder readily dissolves in the discharges within forty-eight hours. The ease with which boric powder dissolves was pointed out as long ago as 1880, when boric acid powder insufflations were recommended for the treatment of ear discharges by Bezold[1] in his textbook.

The use of iodine in the treatment of middle ear suppuration is not new. The first mention of iodine powder in the literature was in 1917, when M. D. Lederman[2] wrote enthusiastically of the results obtained in the treatment of middle ear suppuration by the use of a new iodine powder (Sulzberger's), the formula of which was not disclosed by its maker but which was stated to liberate readily the iodine content. The formula was not disclosed until 1930,[3] and was then stated by Lederman to be a percentage, varying from 0.75 to 10, of iodine in boric acid powder; he insisted, however, that the best results could be obtained only with the original Sulzberger powder. An interesting discussion at the Section of Otology of the New York Academy of Medicine followed the reading of Lederman's paper.[4] Lederman read a paper on the same subject at the Second International Congress of Oto-Laryngology at Madrid in September, 1932, but this paper has not yet been published.

In 1919, F. Stoker[5] recommended the employment of bismuth and iodoform powder, 1 to 2, which was said to liberate nascent iodine; unlike iodine and boric powder, however, or even boric powder alone, it did not dissolve readily in the ear discharges, and it blocked up the deeper parts of the meatus. In 1926 F. P. Sturm[6] wrote on the value of nascent iodine in otorrhoea; the method he employed was the local application of hydrogen peroxide drops and the internal administration of potassium iodide, which, when pushed, apparently set free nascent iodine at the point of application of the hydrogen peroxide. In 1926 Fotiade[7] recorded a series of cases of chronic suppurative otitis media successfully treated by instillations of Calot's solution (consisting of guaiacol 1 part, creosote 5 parts, ether 30 parts, iodoform 10 parts, and olive oil 70 parts), which liberated free iodine. Guttman,[8] in 1927, confirmed Fotiade's claims. Joseph C. Beck[9] stated in 1929 that he had treated a series of more than thirty cases of chronic suppurative otitis media with iodine powder (Sulzberger), introduced to his notice by M. D. Lederman; most of the cases dried up, but he considered it was too early to judge of the permanence of the cure. In 1929 M. J. Mandelbaum[10] recorded a number of cases of cure of chronic middle ear suppuration by the instillation of iodized oil. In 1931 N. Asherson[11] published an article on iodine powder in the treatment of chronic otorrhoea, quoting from the article by M. D. Lederman published in America in 1930.[3] He stated that a large number of cases of chronic uncomplicated otorrhoea in children, with a marginal perforation of the drum, could be cured by treatment with 1 per cent. iodine powder, but for most cases he preferred ionization, except for those in which operation was indicated. He considered that the treatment was well worth a trial before recourse to the radical operation. My own experience is that Asherson's conclusions are very much an understatement of the value of iodine powder when the treatment is properly carried out. In the past two years I have found that it cures nearly 95 per cent. of cases of chronic middle ear suppuration, and during that period I have never had to perform the radical mastoid operation except in cases of cholesteatoma and intracranial lesions. In the latest (1932) edition of Logan Turner's standard textbook, *Diseases of the Nose, Throat, and Ear*, J. S. Fraser[12] states:

"Conservative treatment of chronic middle ear suppuration by means of drops and syringing, if efficiently carried out, results in cure in 50 per cent. of cases. A further 25 per cent. may be cured by special methods, such as syringing through the Eustachian tube, intratympanic syringing, or the use of zinc ionization. Most of the remaining 25 per cent. require operation (radical or modified radical mastoid operation). Out of 1,893 cases of chronic middle ear suppuration seen at the Royal Infirmary, Edinburgh, during five years, 424 came to mastoid operation."

Two patients of mine, who had apparently an idiosyncrasy to iodine, could not tolerate the iodine powder (even as the 0.75 per cent.), and in one of these cases the irritation persisted for several days after the powder had been mopped out with liquid paraffin. The iodine powder has cleared up several persistent fistulas, and it is also a very useful dressing in the later stages of the after-treatment of the mastoid operation. The following are brief notes of some typical cases.

Case 1.—A man, aged 28, was seen in November, 1930. He had had discharge from the right ear for three months following a severe cold; this troubled him very much, since he was already deaf (an old-standing chronic middle ear deafness) in the left ear. There had been no improvement with syringing and drops. I told him that he ought to have a mastoid operation, but that first we should try the iodine powder. I mopped and sucked out the discharge and insufflated the powder daily for ten days. At the end of that time the discharge had stopped, and his hearing was apparently normal and has stayed so.

Case 2.—A. H., aged 32, had had a radical mastoid operation performed by an aural surgeon, but discharge continued both from the meatus and from the mastoid wound. After some months the wound was opened up and the operation re-done, granulations and more bone being removed. A post-aural fistula remained, with persistent discharge. Vaccines, ultra-violet and other rays, and innumerable different methods of treatment were tried in vain. After insufflation of iodine powder into the fistula every second day for three weeks it healed completely.

Case 3.—R. M., aged 27, had had a zygomatic mastoiditis, and the incision was made well forwards over the zygoma. The post-aural wound healed well, but a large fistula to the zygoma persisted, with abundant discharge. Fomentations, syringing with eusol, and other treatments had no effect; on opening up the wound there was no sequestrum, and six weeks after the operation the discharge showed no signs of abating. The wound was then filled daily with the iodine powder and within a week it was completely healed.

Case 4.—A man, aged 50, had had a radical mastoid operation eighteen years previously. The ear seemed quite well until two months previously when it began to discharge after influenza. A mass of cholesteatomatous debris was syringed out of the ear—the syringing caused intense giddiness—and a foul discharge continued. The discharge was mopped out and iodine powder insufflated. Three days later the discharge was much less. The cavity was then filled with iodine powder and a week later the discharge had cleared up and the old mastoid wound cavity remains dry and healthy.

Case 5.—A boy, aged 11, had had discharge from both ears for the past six years, after scarlet fever. He had had his tonsils and adenoids completely removed, and the ears had been treated by syringing, drops, and ionization, but without improvement. On March 1st, 1932, the debris was syringed out of both ears (this made the patient sick and giddy), and he was given drops of boric acid in spirit 10 grains to the ounce. On March 7th both ears were mopped out and iodine powder blown in. On March 14th the left ear was dry and the discharge from the right was slight; iodine powder was again blown into both ears. When seen on March 21st both ears were dry and apparently healed.

Case 6.—A clerk, aged 24, had had a discharging left ear for six weeks. When seen on April 9th, 1932, there was a polyp coming from the postero-superior part of the drum. The discharge was mopped away and the polyp touched with silver nitrate; iodine powder was then blown in and prescribed for the patient, who used it daily. When seen a week later the polyp had disappeared and the discharge was slight. A week later still the ear was quite dry and has remained so.

Case 7.—A youth, aged 16, had had his left ear discharging for some years. On June 2nd, 1932, the discharge was mopped out and iodine powder blown in; the powder was prescribed to be used daily. When seen on June 16th the ear was quite dry and healthy.

Case 8.—A schoolgirl, aged 14, had had her right ear discharging for a month, and when seen on July 21st, 1932, it was discharging freely. It was mopped out, and iodine powder blown in, and prescribed to be used daily. When

seen on August 4th the discharge was slight, and a week later the ear was quite dry.

M. D. Lederman[3] describes the iodine powder as an intimate association of iodine with boric powder prepared by mixing an iodine solution with dry, finely powdered boric acid and evaporating the solvent. I have found the following method simple and effective:

℞ Iodi resublimatae ... ... gr. 3.6
Pulv. acid. boric. ... ... ad ʒj
Sig. Iodine 0.75 per cent. in boric powder; use in a powder blower as directed.

Rub down the iodine with a few drops of spirit. vini rect. until solution is effected, and gradually incorporate the finely powdered boric acid. The preparation should be freshly prepared and kept in a well-closed container to avoid, as far as possible, loss of iodine by volatilization.

Practitioners and hospital colleagues to whom I have introduced the method have taken it up with enthusiasm. At one institution for children which I visit as a consultant, ionization was formerly the favourite method of treating ear suppuration, but it is now discarded in favour of this newer, much simpler, and more effective treatment.

RELATIONSHIP OF SYPHILIS AND YAWS *

BY

D. B. BLACKLOCK, M.D.

PROFESSOR OF PARASITOLOGY, UNIVERSITY OF LIVERPOOL

The problem as to the identity or otherwise of yaws and syphilis has assumed great importance in recent times owing to advances in treatment. Those who hold that yaws and syphilis are two entirely distinct diseases will have no hesitation in treating yaws with a few injections of any suitable drug which will get rid of the skin eruption. Those, however, who think that yaws is the same disease as syphilis, and those also who hold that, without being identical, yaws protects to some extent against syphilis, will regard such treatment of yaws as fraught with considerable risk. It is a matter of great importance to our tropical possessions that a decision on this question should be reached as soon as possible. As a result of my investigation into the evidence it does not appear possible to assert here that there is only one disease. On the other hand, the more closely one examines the differential points which are set out in the textbooks on tropical medicine the less convinced one becomes that the criteria are sufficient for differentiation. The onus of proof rests on those who assert that there are two diseases and not simply modifications of a single disease.

In the short time available to-day it is impossible to deal with the long list of so-called differential points set out in the textbooks. For the purpose of opening this discussion only those have been selected which are most stressed by authors, and which form the essential arguments, the two most important being the "congenital" and the "severe nervous system involvement."

* Read in the Section of Tropical Medicine at the Centenary Meeting of the British Medical Association, London, 1932.

THE "CONGENITAL" ARGUMENT

The congenital contrast is usually set out in the tables as follows: yaws, not congenital; syphilis, congenital. The statement that yaws is not transmitted transplacentally is accepted by the majority of workers, but there are a few records which suggest that such transmission occasionally occurs. In regard to the statement that syphilis is congenital, are we justified in accepting this as correct? I think not; syphilis is not the name of a single clinical entity: it is divisible into several clinical divisions, and to some of these the statement does not apply. We may divide syphilis into categories thus:

1. Acquired venereally, with or without chancre.

2. Acquired non-venereally. This again may be divided into: (*a*) adult, with extragenital primary sore; (*b*) infantile, with extragenital primary sore, rarely genital; and (*c*) congenital, with no primary sore.

The general dictum "syphilis congenital" may be applied to the first main group, venereally acquired syphilis, provided we qualify it with reservations to the effect that transmission to the partner in marriage does not inevitably occur, that once infected the mother does not necessarily transmit to her offspring, that if she does transmit she may do so irregularly, not to one child but to the next, and even to one only of twins. In the second main division I have not been able to find figures which show the results as to transmission transplacentally of adult or infantile syphilis with extragenital chancre. Information concerning the latter would have been useful for our present purpose, since it is a group very comparable with yaws. Some authors consider that syphilis acquired soon after birth gives rise to stigmata similar to those of congenital syphilis. In the third division of the non-venereally acquired group—namely, congenital syphilis—we have the evidence of many observers who are agreed that transmission transplacentally in such cases is a very exceptional occurrence; some even go so far as to suggest that there is no properly authenticated case of such transmission.

Here, then, in congenital syphilis, and probably we may include the acquired syphilis of infancy, we have a volume of the disease, and a very important one for our present purpose, to which the dictum that syphilis is congenital cannot be applied. Reverting to yaws and syphilis it seems to introduce a fallacy if we compare yaws, which is a disease of early childhood particularly and acquired non-venereally, with syphilis as a whole. We ought at least to refrain from comparing it with venereally acquired syphilis of adults; the comparison should be limited to those forms of syphilis which affect young children and are acquired non-venereally. Instead of the antithesis with which we began we should then have: in yaws, transplacental transmission very rarely recorded; in congenital syphilis, and the acquired syphilis of early childhood, transplacental transmission very rarely recorded. When yaws is compared thus with those forms of clinical syphilis with which it appears to be properly comparable the value of the greatly emphasized "congenital" criterion of difference is seen to have no existence.

YAWS AND SYPHILIS AND THE NERVOUS SYSTEM

In the tables the contrast is: yaws, nervous system never seriously affected; syphilis, nervous system prone to infection—for example, tabes and G.P.I. It has been recorded in regard to yaws that tabes and paresis occur in adult natives of Fiji, where syphilis is reputed unknown, but the majority of observers have failed to record these sequelae in yaws areas or have recorded them very rarely. From the statement concerning syphilis, most readers would assume that in syphilis there is always a significant amount of tabes and paresis, such as is recorded in the

case of venereal syphilis, for various countries in Europe and for the white population in America. So far is this from being the case that even in Europe there is a considerable area in which tabes and paresis are conspicuous by their very rarity in syphilitics. In the region of Bosnia and Herzegovina there is recorded an endemic form of syphilis; young children are infected with extragenital primary sore, but tabes and paresis are rarely observed. In America observers find that negroes living under comparatively civilized conditions are much less affected by tabes and paresis than the white population. It does not concern us here whether this difference in incidence is due to race or occupation or the florid nature of the secondary eruption or any combination of these or other factors; what is important to note is the fact that the incidence in negroes is less than in whites. When we turn to the natives of subtropical and tropical climates living at home in their own lands we find a remarkable state of affairs. The evidence from innumerable regions and observers shows that tabes and paresis, as the results of syphilis, are excessively rare among these populations. The rarity of tabes and paresis, in spite of great prevalence of syphilis, in Malaya, India, British Guiana, the Panama zone, and the east and west French colonial territories is the subject of continual comment. The records of these areas approximate closely, though they do not quite equal, that of Cook in Uganda, who, in 100,000 syphilitics, never once found a case of tabes or paresis.

Thus all the evidence goes to show that there are vast areas in the Tropics and subtropics, with very large populations affected with syphilis, where the dictum that syphilis produces tabes and G.P.I. cannot be used in the sense implied. Indeed, the absence of these two sequelae of syphilis focuses the attention of all observers. Here again it appears to me that the constructors of the tables of differences between yaws and syphilis introduce a fallacy by comparing things which are by no means strictly comparable. Yaws, peculiarly a disease of children and one acquired non-venereally and in the Tropics, should not be compared with syphilis in general; it ought to be compared with the syphilis of native children acquired non-venereally in tropical regions. In the absence of figures for such infections we should at least compare it with syphilis as it occurs in the Tropics. Even on this somewhat unsatisfactory basis the result is highly suggestive, and if recorded in the usual form is: in yaws of tropical countries, tabes and paresis very rarely recorded; in syphilis in tropical countries, tabes and paresis very rarely recorded. When put on even an approximately comparative basis, therefore, the incidence of tabes and paresis does not assist us in distinguishing yaws from syphilis.

Primary Lesions.—Another argument frequently used is that in yaws the sore is extragenital, whereas in syphilis it is usually genital. I should like to suggest that this point, although much emphasized by all writers, has no standing whatever as a differential criterion. It is simply the statement of an epidemiological fact. By the adoption of this identical formula a person can prove to his own satisfaction, if he desires to do so, that infantile acquired syphilis in England is quite a separate disease from venereal syphilis here, because the former has an extragenital primary lesion while in the latter the primary lesion is usually genital.

Itching.—The next point stressed by some authors is that in yaws itching is common whereas in syphilis it is rare. The evidence, however, whether in descriptions of yaws or syphilis, is very inconclusive, as regards both the primary lesion and the secondaries. The qualifications as to the degree and kind of itching in various conflicting statements make it obvious that there is little agreement. One important fact—namely, that the lesions in yaws itch more than the corresponding lesions in syphilis—appears to be overlooked. The skin of a naked native child in the tropical rural areas is constantly exposed to a whole series of agencies, such as biting insects, skin-penetrating larvae, and abrading and injurious objects, any or all of which are apt to initiate pruritus. From my observations of groups of children in tropical villages I formed the opinion that itching is almost a property of the skin of the native child, and that degrees of it are not likely to help us in differentiating yaws from syphilis.

Occurrence of Alopecia.—It has been stated that alopecia never occurs in yaws but may occur in syphilis. So far as I have been able to observe, the occurrence of alopecia among the negroes in their own countries is extraordinarily rare; in this there is a contrast with the white people of Europe and America. In so far as alopecia attributable to syphilis is concerned the evidence from the latter countries is very conflicting. It is unfair to contrast yaws alopecia with any other than alopecia resulting from child syphilis in the natives of the Tropics; it does not appear from the literature which I have been able to consult that figures exist on this aspect of the problem. It would be of great interest to ascertain whether alopecia exists in, and constitutes a character of, even venereal syphilis in the Tropics.

MUMPS AND APPENDICITIS

BY

JAMES DONNELLY, L.R.C.P. AND S.

AND

JAMES BAGOT OLDHAM, F.R.C.S.

In the *Epitome* published with the *British Medical Journal* of July 2nd an abstract was given of an article by Sandler and Finne (*Archives of Pediatrics*, March, 1932) entitled, "An unusual case of epidemic mumps complicated by gangrenous appendicitis." These authors state that only five examples of this combination of diseases have been described in the literature, and we are therefore encouraged to report the following case:

HISTORY OF CASE

On May 25th, 1932, a boy, aged 7 years, was seen by one of us (J. D.). He had been "off colour" for some days; on the 23rd he had complained of pain on swallowing, and his parents had noticed that his face was swollen. A week previously a school friend had developed mumps. On examination both parotid and submaxillary glands were found to be swollen and tender. The temperature was 100° and the pulse rate 100. The appetite was lost. A diagnosis of mumps was made and the appropriate treatment instituted. On May 26th the symptoms had increased a little, but two days later the pain and swelling were diminishing and the appetite had returned. On the morning of the 29th the boy seemed to be convalescing well, the bowels had opened, the temperature was 98.8° and the pulse rate 90. That evening he complained of pain in the epigastrium, vomited, and became restless. On examination some muscular resistance was noted on palpating the upper abdomen. The temperature had risen to 100°, the pulse rate remained at 90. There was a slight glycosuria. A tentative diagnosis of pancreatitis was made.

On the next day (May 30th) the temperature was still 100°, but the pulse rate had risen to 98. Vomiting had stopped, but there was anorexia. The pain was still in the epigastric region, but was apparently increased, as was the muscular resistance. There was some tenderness on palpation of the umbilical region. The bowels had not moved since the previous morning. On May 31st the temperature was 100° and the pulse rate 100. The pain, which was still epigastric, had diminished, but the tenderness and rigidity had increased. The bowels were opened. On the morning of June 1st there

was very little pain, but there was marked tenderness and rigidity, more especially in the region of the right iliac fossa. There was some frequency and pain on micturition. A diagnosis of acute appendicitis was made. At three o'clock on the same day the boy was seen in consultation by both of us. The temperature was 100.4°, the pulse rate 136, and the respiratory rate 28. The boy denied that he had any pain. The abdomen did not move on respiration, and was slightly distended. There was marked tenderness and rigidity over the whole of the lower abdomen, but more especially over McBurney's point. There was no cutaneous hyperaesthesia. On rectal examination there was extreme tenderness in the recto-vesical region. The swelling of the salivary glands had diminished greatly, especially on the right side. A diagnosis of acute appendicitis with perforation and peritonitis was made.

THE OPERATION

The boy was immediately transferred to the General Hospital, Birkenhead. At 4.30 p.m. the abdomen was opened (J. B. O.) under gas-and-oxygen anaesthesia through a split muscle incision. A large quantity of thin, purulent, slightly offensive fluid gushed out of the incision, and it was found that the whole lower abdomen and pelvis was involved in the peritonitis. The appendix, which was gangrenous and perforated, was removed. A split rubber drain was led down into the pelvis through a suprapubic stab incision. The appendix incision was closed with a small piece of rubber glove inserted down to the muscle layer.

Convalescence was uneventful. The pulse rate and temperature quickly returned to normal, the bowels were opened on the third day and continued to act daily until the boy left hospital on June 13th. He is now in perfect health.

COMMENTARY

The details of this case correspond very closely with the history of the cases reported by Simonin (1903), Jalaguier (1909), Rosenow and Dunlap (1916), Benassi (1925), and Sandler and Finne (1932). The case reported by Gaudier and Swynghedauw (1925), and mentioned by Sandler and Finne, should not be included, as the parotitis appears to have been a suppurative condition secondary to acute appendicitis and arising after operation.

The aetiology of mumps is still a mystery, and the virus remains unknown. From the frequent occurrence of orchitis, pancreatitis, etc., it appears to attack certain glands, with a special predilection for the parotids. Opportunities to determine the morbid condition have been few, but Virchow described the condition of the gland as one of inflammatory serous and cellular infiltration of the interacinous and periacinous connective tissue, the parenchyma being but slightly involved. While the parotid glands are especially affected the submaxillary salivary glands are usually involved, the sublingual glands less often. The lymph glands at the angle of the jaw and the parotid lymph gland are enlarged. Koplik states that in every case he observed there was distinct angina and swelling of the tonsils. Enlargement of the lachrymal glands has been noted in many cases. Orchitis is a very common complication, and usually occurs about the eighth day. Less commonly ovaritis, mastitis, pancreatitis, and enlargement of Bartholin's glands are noted. It is generally admitted that these complications are metastatic infections arising from the primary foci in the salivary glands. Is appendicitis another possible metastatic complication of mumps or is their association simply a coincidence? It is interesting to note that in the case recorded above, and in all the cases previously reported, the onset of the acute appendicitis has occurred a week or thereabouts after the parotitis started. In the words of Benassi: "In these cases there is no question that the appendicitis developed at the height of the parotitis, and with some doubt and reserve there is enough evidence to support the following conclusion: that the virus or organism which lodges in Stenson's duct travels to the appendiceal region by way of the digestive tract or by way of the haematogenous or lymphatic systems."

Memoranda

MEDICAL, SURGICAL, OBSTETRICAL

BILATERAL SUPERIOR THORACIC GANGLION NEURECTOMY IN PARKINSONISM

The results obtained in the case reported below are thought to be of sufficient interest to justify publication.

CASE RECORD

The patient, a woman aged 34, had "flu" in 1924, and was admitted some time later with post-encephalitic Parkinsonism to the Maudsley Hospital, where she was treated for ten weeks. For the last seven years she has been treated at home with injections of hyoscine (grain 1/75 twice daily). For the two months previous to admission she was unable to feed herself or to walk.

On July 7th, 1932, she was admitted to the Archway Hospital, Highgate. She had marked tremor and rigidity, a mask-like expression, slow cerebration, excessive salivation, a greasy skin, and an advanced degree of talipes equino-varus in the left foot. An attempt was made to substitute tincture of stramonium for the hyoscine, but this was strongly resented by the patient, who became very depressed and unable to sleep.

Treatment

The operation described by N. D. Royle in the *Journal* of June 11th, 1932, is stated by him to decrease the tremor of the homolateral hand, and, by increasing the cerebral circulation, to decrease the spasm of the contralateral leg and to improve the mentality of the patient.

On July 18th the right superior thoracic ganglion was removed after a deep dissection in the root of the neck, according to Royle's description. There was no difficulty in finding the ganglion, which was removed and sent for section. On August 30th, at the request of the patient and her mother, a similar operation was performed on the left side. A previous subcutaneous tenotomy had been performed on August 18th to correct the deformity of the left foot.

Results

Immediate.—This was the same after each operation. While the patient was still under the anaesthetic the pupil became contracted and the sweating of the face ceased on the homolateral side. After recovery from anaesthesia the patient stated that she felt much more alive, and smiled when spoken to. On the homolateral side the tremor had disappeared at rest, and was markedly diminished on performing voluntary movements; the sweating of the face had ceased, and the salivation was lessened. Ptosis of the eyelid was present, and a decrease of the labio-nasal fold was noticed. The homolateral arm had a well-marked vaso-dilatation, with a rise of temperature. No difference was noticed in the rigidity of the legs.

One Week Later.—The ptosis of the eyelid and the vaso-dilatation of the arm had disappeared. The patient was able to drink from a glass of water held in either hand, and her cerebration was much quicker. There was no tremor at rest; she could read a book for longer periods, and she smiled when spoken to.

Six Weeks Later.—There was no tremor at rest. The patient could feed herself, and stated that she felt brighter than before the operation. She now has no injections of hyoscine, and is taking extract of stramonium. She eats and sleeps well, and her attacks of depression are much less frequent. The wounds in the neck show only as a faint scar. No change can be noticed in the rigidity of the legs. The patient is being fitted with surgical boots, but at present walking is not good, due partly to deformity and rigidity, and partly to wasting of the limbs from disuse.

COMMENT

The case was an advanced one of eight years' standing, and as a result of the operation there is a greater improvement in the mentality of the patient than could have been obtained by medical treatment alone. The

marked alleviation of the tremor allows the patient to feed herself and to lead a more enjoyable life, and both the patient and her relations are pleased with the result of the operations. They have, however, failed to alter the spastic condition of the legs, and whether the improvement at present noticed in the tremor and mentality will be maintained it is not possible to say.

The operation would appear to be indicated only in cases which seem to be stationary, and in which, in spite of the exhibition of large doses of extract of stramonium, the patient is incapacitated by tremor of the hands and complains of mental deterioration.

I wish to express my thanks to Sir Frederick Menzies for permission to publish this case, and to Dr. H. O. West, medical superintendent of the Archway Hospital, for his assistance.

HENRY A. KIDD, F.R.C.S.Ed.,
Highgate. L.R.C.P.Lond.

DEAD FOETUS IN ABDOMINAL CAVITY

RUPTURE OF PREVIOUS CAESAREAN SCAR

I consider the details of the following case to be worthy of record.

A patient, aged 31, had had a Caesarean section performed fourteen months previously at another hospital, owing to contracted pelvis. She became pregnant again, and arrangements were made to admit her to this hospital for another Caesarean section just before term. Three weeks before term she was seized with pain at 4 a.m., which she stated to be continuous and not in any way to resemble labour pain. She was admitted to hospital seven hours later. Her temperature was subnormal; pulse 108. The abdomen was acutely tender to palpation and rigidity was present. A vaginal examination was not made. At operation the surgeon, having made the usual incision (in the median line, down to peritoneum), noted that blood escaped out of the abdominal cavity, also that lying free in the abdominal cavity was a large sac. This proved to be the intact bag of membranes, containing the foetus. The placenta (attached to the bag of the membranes) was also lying in the abdominal cavity. The sac was removed entire and opened, a dead foetus being found inside. The uterus was then examined, and was found to have ruptured along the entire length of the previous (Caesarean) scar.

I am indebted to Dr. A. Lloyd Davies for permission to record the above details.

IRENE P. ROWLANDS,
Wrexham and East Denbighshire War Memorial Hospital. House-Surgeon.

Reports of Societies

TREATMENT OF THE ANAEMIAS

At a joint meeting of the Sections of Therapeutics and Medicine of the Royal Society of Medicine on January 10th, with Dr. H. MORLEY FLETCHER in the chair, a discussion on the treatment of the anaemias was opened by Dr. L. J. WITTS.

Dr. Witts said that in the treatment of the microcytic hypochromic anaemias different chemical combinations of iron had been found to vary in their therapeutic activity. In pernicious anaemia the reticulocyte count was an index of progress under treatment, but with the microcytic anaemias there was no such short cut by which the value of a remedy could be assessed. Ferrous salts of iron appeared to be much the most potent, especially when achlorhydria was present, and following them, in order of potency, came scale preparations, ferric salts, and organic compounds, the last being almost without effect. Both iron and ammonium citrate and Blaud's pill could be given in large doses. He had found that the minimum effective dose of Blaud's pill to ensure success in the treatment of microcytic anaemias could be fixed at 45 grains a day. He had not found it necessary to add arsenic, copper, or other inorganic salts to the diet of ordinary adults in this country in order to make iron therapy effective. Remarkably large doses of iron might be necessary in refractory cases, especially in pregnancy; 80 per cent. of cases of microcytic anaemia, however, improved on Blaud's pill in doses of only 15 grains a day. A new preparation of iron for injection had been included in the *B.P.C.* The therapeutic dose of iron by injection was 16 to 32 mg., and the toxic dose 48 mg.—an increase of only 50 per cent. With such a small margin of safety he preferred to avoid injections of iron. At the climacteric menorrhagia might nullify all attempts at medical treatment; in such cases the induction of an artificial menopause gave satisfactory results, and the anaemia did not appear to recur. In the treatment of pernicious anaemia the question of cost was often overlooked in selecting a remedy. At the present time desiccated stomach was the cheapest and most effective treatment for the anaemia and the associated cord changes.

Professor L. S. P. DAVIDSON referred to the value of a satisfactory classification of anaemias in facilitating the adoption of correct therapeutic measures. He went on to say that during the recuperative stage of pernicious anaemia there was no iron retained in the organs, as he had been able to demonstrate in one of his patients who was killed by a bus. For this reason he thought patients during the recuperative stage should be treated with whole liver, not merely with liver extracts. Potent extracts for the cure of pernicious anaemia could be obtained from fish livers, as he had recently been able to show, and it was probable that preparations of this kind would be put on the market very cheaply. He had used marmite with success in one or two cases of pernicious anaemia, but in several others it had had no effect. In the treatment of the microcytic anaemias he had obtained dramatic improvement by the use of solid ferrous chloride, 5 grains daily; the results had been as good as those obtained with Blaud's pill, 60 grains daily. Unfortunately ferrinol, the proprietary preparation of ferrous chloride on the market, was expensive, the cost of treatment working out at 4s. a day.

Dr. H. LETHEBY TIDY suggested that anaemia might be exaggerated in some cases by exhaustion of the bone marrow and other blood-forming organs. Cases of "acute febrile anaemia," of polycythaemia in which anaemia ultimately developed, of primary purpura with anaemia preceding haemorrhage, of pernicious anaemia which failed to react to treatment, and of the pernicious anaemia of pregnancy, might all be examples of such exhaustion of the haematopoietic system. He thought such cases might well be treated by blood transfusion, which might start them on the way to recovery, and even save life.

Professor FREDERICK LANGMEAD said he had asked himself why the dosage of iron necessary for effective treatment of the microcytic anaemias should be so much in excess of the normal iron requirements of the body. Dr. Bourdillon, whom he consulted, had suggested that it was associated with the *p*H of the duodenal contents. When achlorhydria was present the *p*H of the duodenum would naturally be raised. He thought that the dosage of iron might possibly be reduced to within ordinary therapeutic limits if it was given with sufficient hydrochloric acid or ammonium chloride to reduce the *p*H of the duodenal contents.

Dr. DOROTHY HARE said that injections of iron had been given to a patient with microcytic anaemia over a period of nineteen days without benefit; iron and ammonium citrate was then given, and marked improvement followed at once.

Dr. JOHN WILKINSON said that extract of hog's stomach was certainly the most effective preparation for the treatment of pernicious anaemia. With critically ill cases the quickest results were obtained with injections of liver preparations, but the preparations available for this purpose were extremely variable. In the treatment of microcytic anaemias he had tested the effects of copper and manganese, both separately and in addition to iron, and had reached the conclusion that iron by itself gave the best results. He thought it was doubtful whether enough acid could be given by mouth to affect the *p*H of the duodenal contents. Dr. SINCLAIR MILLER had found

that many of his elderly pernicious anaemia patients would rather have a weekly or fortnightly injection than take liver or stomach extract by mouth daily. They seemed to keep well under this treatment. Dr. E. N. ALLOTT mentioned two cases in which numbness of the fingers had developed in patients with pernicious anaemia after they had been put on liver treatment. He wondered whether liver therapy encouraged the development of subacute combined degeneration. The CHAIRMAN wanted to know whether whale liver had been tested for an extract suitable for the treatment of pernicious anaemia.

Dr. WITTS, replying, said that in his experience symptoms of subacute combined degeneration improved on increased doses of stomach extract. Where there was iron shortage in the recuperative stage of pernicious anaemia he thought iron, not liver, should be given, since few patients would eat liver twice a day for life. Professor DAVIDSON thought the incidence of subacute combined degeneration was increasing, and he had not been able to obtain any marked improvement in patients with signs of this condition by increasing the doses of liver extract.

X RAYS IN DIAGNOSIS OF PLACENTA PRAEVIA

At a meeting of the Edinburgh Obstetrical Society held on December 14th, 1932, with the president, Dr. JAMES YOUNG, in the chair, a paper was read by Professor MUNRO KERR and Dr. W. G. MACKAY (Glasgow) on the diagnosis of placenta praevia, with special reference to the employment of *x* rays for this purpose.

Professor Munro Kerr introduced the subject by referring to the high percentage of maternal deaths due to placenta praevia, and stated that in order to maintain a low maternal death rate it was of the greatest importance that the most suitable method of treatment should be selected for each individual case. He referred to the great difficulty not only of diagnosing the variety of placenta praevia that was present, but also of the diagnosis between a placenta praevia and an accidental haemorrhage. He referred to various methods of diagnostic value, but showed that even by applying all these methods diagnosis was often doubtful. He therefore considered that any method of diagnosis which would not only differentiate placenta praevia from accidental haemorrhage, but would also show which variety of placenta praevia was present, would be of the greatest value, and he called upon Dr. Mackay to demonstrate a method which they had investigated together.

Dr. Mackay gave, in the first place, a short summary of previous investigations which had been carried out in order to locate the position of the placenta in the uterus, and came to the conclusion that the only one which had been at all satisfactory up to the present was that of Manees, Miller, and Holly, who had injected strontium iodide into the amniotic sac of pregnant women. The placenta which projected into the cavity produced a defect at the edge of the shadow when the uterus was pictured from the correct angle. Professor Munro Kerr and Dr. Mackay had tried this method on ten cases, but as the foetus had died in three it was given up, and uroselectan B, which was non-toxic and non-irritant, was substituted for strontium iodide; 20 c.cm. of this substance was found to produce a suitable shadow, and in ten cases in which the procedure was carried out no untoward effects occurred either to the foetus or to the mother, though there was no doubt that the injection had a great tendency to terminate pregnancy. The technique of the operation was then described fully, and the question of taking at least two radiograms—one postero-anterior and the other lateral—was insisted upon so as to be sure of getting a full view of the indent made by the placenta. If this was not sufficient, in doubtful cases lateral radiograms had to be taken as well. Dr. Mackay then showed a number of radiograms on the screen which demonstrated the position of the placenta not only in normal cases, but also in cases of placenta praevia, when it could be ascertained exactly how much of the placenta was in the lower uterine segment and covering the os. The speaker then explained various errors which had to be excluded, such as gas in the bowel and the presence of two sacs. He also showed how *x* rays could, in certain cases, make possible a diagnosis of the sex of the child, and also show whether any coils of cord were round the child's neck.

Radiotherapy in Gynaecology

The second paper, on some aspects of radiotherapy in relation to gynaecology, was read by Dr. J. B. KING. He first dealt with the question of radiotherapy in regard to cancer of the cervix, and explained the principal methods of application. He also reviewed statistics from various Continental sources, and compared them with those of Bonney for operation in such cases. It was Dr. King's opinion that the problem of the treatment of the primary lesion was solved, and that the minor variations of technique now used in different clinics did not matter greatly so long as the cervix received some 4,000 to 5,000 milligram hours, suitably filtered. It was, however, the treatment of the parametrium and the involvement of glands that had still to be investigated thoroughly in order to improve the mortality rate, which, even in the best statistics, was about 51 per cent. in early cases. Dr. King considered that the only line along which this problem could be attacked was that of *x*-ray therapy, and it was certain that the highest percentage of cures had arisen in the clinics where *x* rays had been used as an adjunct to radium. He mentioned that 400,000 volts—almost double the dose now available—would soon be possible, and he thought that with this dose the pelvis could be irradiated very completely to cause a widespread irradiation of the carcinoma. The radium bomb might also be of use for this purpose. There was no danger in carrying out radium or *x*-ray treatment immediately after one another for cases of uterine carcinoma, and he considered that the so-called *x*-ray sickness, due to intensive radiation, was a thing of the past, and did not occur with present-day methods. He next discussed the question of radiotherapy for carcinoma of the body of the uterus and of the ovary, and concluded that, though radium might be of use in the former, it was not likely to be of any avail in the latter. The question of radiotherapy for fibroids was then advanced, and Dr. King mentioned several of its advantages over operation in such cases. The treatment of sterilization by radiotherapy and the treatment of functional menorrhagia was also touched upon, and the suitability of *x* rays and radium in such cases was discussed. Dr. King did not believe in the cure of amenorrhoea by so-called stimulation doses of *x* rays to the ovaries, as he considered no such action as slow stimulation was caused by radiation. He thought that these cases were probably due to a destruction of persistent cystic follicles rather than to any stimulation of ovarian secretion. Finally, he touched upon the treatment of some cases of menorrhagia associated with symptoms of hyperthyroidism which had improved very markedly simply by radiation of the thyroid.

A quarterly court of the directors of the Society for Relief of Widows and Orphans of Medical Men was held on January 4th. In the absence of the president Dr. W. Culver James, the senior vice-president, took the chair. Grants amounting to £1,975 were voted for the half-yearly payments to the widows and orphans in receipt of relief. Of this amount £112 10s. was for special grants to orphans to enable them to continue their education, or assist them with their expenses in connexion with the careers they were embarking on. The expenses of the quarter were £88 2s. 6d. Last December £640 was distributed as Christmas presents. At the present time there are fifty-two widows and seven orphans in receipt of relief. Six new members were elected at the meeting, and the resignations of two were received and accepted. Membership is open to any registered medical practitioner who at the time of his election is residing within a twenty-mile radius of Charing Cross. Application forms for membership and terms of annual subscription may be obtained from the secretary, who attends at the offices of the Society, 11 Chandos Street, W.1, each Wednesday and Friday between 4 and 5 p.m.

Reviews

TREATMENT OF SYPHILIS

So many people appear to think that syphilis can be cured by a few injections of arsenobenzol that the appearance of such a book as *The Treatment of Syphilis*,[1] by J. F. SCHAMBERG and C. S. WRIGHT, is to be welcomed, more especially as the authors have gone deeply into their subject, delved into the literature, and presented their thesis as fully as anyone could desire. It seems a pity that they should have confined themselves almost entirely to the treatment of the individual, and neglected to discuss the matter as a world problem: it should be more important to deal with the disease as a social evil than to treat the individual.

The four principal drugs used in anti-syphilitic medication—mercury, bismuth, arsenic, and the iodides—are dealt with in that order. Mercury is largely of historical interest, though there are still many occasions when it may be used with advantage; we gather that it has retained its popularity more in America than in this country. No fewer than ninety-eight pages are devoted to this drug, as against fifty-four to bismuth—which seems somewhat surprising in view of the fact that bismuth has very largely superseded mercury, that the former has most of the advantages and few of the disadvantages of the latter, and that a voluminous literature has sprung up around it in the last ten years. Nevertheless, the authors never fail to ascribe to bismuth its full value in routine treatment. As to whether it ever reaches the spinal fluid in appreciable amounts they retain an open mind, leaving the reader to decide from amongst the authorities quoted.

The arsenobenzenes, of course, receive more extended notice—208 pages. It would appear that the authors favour the intravenous route and the "neo" preparation where applicable, and they are disciples of the concurrent use of bismuth, all of which is in accord with the best-informed opinion in this country. The sections on the unfavourable reactions which may follow are good, but more might have been said about the treatment of jaundice and dermatitis. The authors rightly stress the fact that neuro-recurrences are due to an insufficiency of the drug, and not to the action of the drug itself. They are evidently pleased with the new drug bismarsen (bismuth arsphenamine sulphonate). The iodides have their uses, but they are limited, and it is stressed that they have no spirochaeticidal action. A useful chapter is devoted to prophylaxis, and the authors evidently are against the oral use of stovarsol, preferring to wait and watch. The treatment of the various types of syphilis—early, latent, visceral, and nerve—is eminently sound; if treatment were always given in adequate amount in the early stages there would be far less nerve syphilis. In general paralysis much is to be hoped for from endothermy fever, which appears to give results at least as good as malaria, with less risk. Intraspinal treatment for nerve syphilis—almost superseded in this country—still seems to have many adherents in America. Cisternal puncture would appear to be a simple affair, and less likely to be followed by unpleasant after-symptoms than lumbar puncture, yet it is very little used in our own clinics.

Speaking generally, this book presents views that are orthodox, and very much in accord with opinion in England. In many cases a number of authorities are quoted and various methods discussed, the authors indicating their own preferences. It is curious that while the pain which may be caused by intramuscular injections is mentioned over and over again, it does not seem to have occurred to the authors that there is such a thing as deep subcutaneous injection; this is particularly useful in the administration of sulpharsphenamine. Many of the illustrations are poor and are not in agreement with the text, and some are misplaced. The bibliography appears to be adequate, and is for the most part given in the text. The book can be recommended for reference purposes; but its standard of literacy is, frankly, very low, as shown in the following sentence on page 494: "The failure to obtain fluid is usually not always due to failure to properly enter the spinal canal." It is a pity that such a very large number of grammatical and typographical errors have been allowed to pass uncorrected.

[1] *Treatment of Syphilis*. By Jay F. Schamberg, A.B., M.D., and Carroll S. Wright, B.Sc., M.D. New York and London: D. Appleton and Co. 1932. (Pp. xxiv + 658; 62 figures. 42s. net.)

A MANUAL OF BACTERIOLOGY

Hewlett's *Bacteriology*[2] is one of the standard English works on the subject. First published in 1898, it now appears in its ninth edition—an ample testimony to its worth. In the preparation of this new edition Professor HEWLETT has had the collaboration of Professor JAMES MCINTOSH. The whole book has been overhauled and brought up to date, and it can be said without reservation that the result of their labours is a sound, reliable, and readable account of the subject. The general arrangement of the book remains unaltered. It commences with a short introduction and then passes to a general consideration of bacteria, their nature, classification, biology, and relation to disease. Following this are two chapters devoted to technical considerations—laboratory equipment, culture media, staining methods, and the like—all of which are succinctly described. A new feature in this part of the book is the section on *p*H, which receives more elaborate treatment than before. Chapter IV concerns the methods of investigating microbial disease, and contains, in addition, sections on the microscope, filterable viruses, and the bacteriophage. The general account of the filterable viruses is good, but it might have been better had it been pointed out that the estimates of the size of the different virus particles are only approximations which might possibly require reconsideration. Chapter V is devoted to infection and immunity, and following this the different groups of bacteria are accorded separate treatment, each chapter terminating with a section on bacteriological diagnosis in which the student will find clear instructions enabling him to carry out the requisite laboratory investigations. These chapters are well arranged, and the information is invariably up to date.

New chapters have made their appearance in this volume: one on undulant fever, contagious abortion, and tularaemia, and another on spirochaetes, which have now been separated from the protozoa. The latter chapter contains detailed instructions for carrying out the Kahn test, in addition to the Wassermann reaction, and, incidentally, a really marvellous dark-ground photomicrograph of *S. pallida*. It is a pity that *S. icterohaemorrhagiae* could not also have been illustrated by a photograph of it in the living state, for there is nothing characteristic about it when fixed and stained. While on the subject of illustrations it may be pointed out that this textbook is most admirably served in this respect. Not only are there numerous good photomicrographs, but there are many drawings which should prove of the greatest value to the student, besides beautifying the book.

Filterable viruses receive generous treatment, a chapter of some forty-six pages being devoted to this subject. The account is a good one, and terminates with a well-balanced consideration of malignant disease from the virus

[2] *A Manual of Bacteriology: Medical and Applied*. By R. T. Hewlett, M.D., F.R.C.P., D.P.H., and James McIntosh, M.D., B.Ch. Ninth edition. London: J. and A. Churchill. 1932. (Pp. ix + 746; 66 figures. 18s.)

standpoint. What was said previously about the illustrations needs some slight modification here, for we cannot congratulate the authors on the photomicrograph of Paschen bodies; it is not at all convincing. Chapters on various diseases not previously considered, the bacteriology of water, milk and food, and disinfection complete the volume. The book is well printed and there is a good index.

ST. BARTHOLOMEW'S HOSPITAL REPORTS

The sixty-fifth volume of *St. Bartholomew's Hospital Reports*[3] is larger than most of its predecessors since 1915, thus resembling those of the pre-war period, and it contains a general index for the volumes xli to lxv, which has been compiled by Mr. W. Girling Ball, one of the honorary secretaries of the editorial committee. There are two *in memoriam* notices, by Dr. Hugh Thursfield and by Professor W. Langdon Brown, of their late colleagues Sir Frederick Andrewes, who for thirty years taught pathology in the medical school, and Dr. James Calvert, whose personality was one of "encompassing kindliness." Two-thirds of the remaining part of the volume deal with malignant disease from one aspect or another, and nearly half of this space is occupied by Mr. Douglas Harmer's admirable Semon Lecture at the University of London in 1931 on the relative value of radiotherapy in the treatment of cancers of the upper air-passages, which has been published as a separate book and was reviewed in our issue of November 19th, 1932. The history and work of the Cancer Research Committee of the hospital, of which Sir Thomas Horder is chairman, are described by the secretaries, Drs. R. G. Canti and W. M. Levitt. This committee is a continuation of the earlier Radiotherapeutic Research Committee, and has, with a generous supply of radium, been able to carry out much work and investigation. Mr. J. Beattie contributes a well-illustrated article on the early diagnosis of carcinoma of the cervix uteri, Mr. R. W. Raven gives a valuable statistical account of secondary malignant disease of bone, Mr. R. Phillips reviews the relations of the lymphocyte and cancer, and Dr. James Maxwell records a case of massive collapse of the lung in bronchial carcinoma. A case of chronic myelocytic leukaemia in a child is fully reported by Drs. C. H. S. Harris and C. F. Harris, who believe that irradiation prevented death in an early stage, and confirm Dr. J. H. Drysdale's opinion of the importance of the red cell count in the *x*-ray treatment of leukaemia. Mr. J. P. Ross writes on causalgia, Mr. H. P. Nelson on subclavian aneurysm following fracture of the clavicle, and Mr. A. M. Boyd on the use of nembutal as a basal hypnotic before general anaesthesia in more than a thousand cases.

JOHNSTONE'S MIDWIFERY

Professor R. W. JOHNSTONE'S well-known *Textbook of Midwifery*[4] has grown out of all recognition. The sixth edition has been reset in clearer type and on a larger page, and now forms a bulky volume that can no longer be accommodated in a reasonably capacious pocket. The characteristics of its earlier stage of evolution have, however, been maintained. The scientific aspects of obstetrics are kept well in the foreground, the embryological portion being particularly clear and well illustrated. The chapter on menstruation has been rewritten, and gives an excellent précis of the present state of our knowledge. The topical metaphor used in summing up ovarian function in relation to the other ductless glands is worth quotation:

> "... the ovary acts as a Ministry of Reproduction under a Coalition Cabinet of all the endocrine glands, and not only exercises a direct control over the sexual and reproductive functions, but represents the needs of the reproductive situation to the other glands, and so influences general metabolism."

The chapter on toxaemias of pregnancy has been recast, and the practical features of the book are kept in their due proportion. On the whole, the matter is well balanced, in spite of the additions and others changes that have been made since its original layout was determined twenty years ago. There is, however, one noteworthy exception in this regard in Section IV (physiology of the puerperium), which contains but one chapter of nine pages covering this subject, the physiology of the neonatal infant, and the management of the mother and child during the lying-in period. The care of the infant, including breast-feeding, is dismissed in little more than a single page, whereas there are two chapters in Section VII (pathology of the puerperium) devoted to the diseases and injuries of the newborn infant and to artificial feeding.

From the point of view of the teacher we regret that the author has not seen his way to take physiology and pathology together in place of the old arrangement of first all of the one and then all of the other. Surely the student obtains a clearer grasp of the subject presented to him in chronological order in clearly differentiated sections of pregnancy, labour, lying-in, and the infant, in which the physiological and the pathological are taken together. An accurate delimitation of the boundary between the normal and the abnormal is difficult and often impossible in midwifery, as is recognized here where Section III includes labour in its various presentations instead of only the physiological. The separation of the clinical course and the factors of labour (Chapters XII and XIII) by intervening sections on the physiology of the puerperium and the pathology of pregnancy from faults of the powers and passages (Chapters XXIX and XXX) may also be instanced as a diversion that cannot aid easy assimilation. But preference for another arrangement does not imply any lack of appreciation of the sound teaching throughout this deservedly popular textbook.

FRENCH CLINICAL LECTURES

The volume of twenty lectures[5] delivered at the Charité Hospital, Paris, by a corresponding number of physicians, by no means confined to Paris, on present-day clinical problems, is the third brought out under the supervision of Professor ÉMILE SERGENT, who contributes an article, with radiograms, to show that tuberculosis may spread by the lymphatics from primary foci in the mediastinum and neck to the lungs. The effect of influenza on tuberculosis, especially in activating quite latent pulmonary tuberculosis, is discussed by Dr. Francis Bordet, who reviews the divergent opinions on this controversial problem. The indications and contraindications for intervention in spontaneous pneumothorax form the subject of a lecture by Dr. P. Pruvost, and the methods of treating vomicae of the apex of the lung, of the generously illustrated article by Dr. F. Dumarest of Hauteville. There are two interesting lectures on unusual, or at least rarely recognized, manifestations of congenital syphilis: Professor J. Dechaume of Lyons mentions that in his school the pulmonary lesions due to the *Treponema pallidum* are fully accepted, whereas in Paris there is some degree

[3] *St. Bartholomew's Hospital Reports*, vol. lxv. London: John Murray. 1932. (Pp. xxv + 317, with a general index to vols xli–lxv, pp. 1-42; 47 illustrations. 15s. to subscribers, 21s. net to non-subscribers.)

[4] *A Text-Book of Midwifery*. For Students and Practitioners. By R. W. Johnstone, C.B.E., M.A., M.D., F.R.C.S.Ed., F.C.O.G. Sixth edition. London: A. and C. Black, Ltd. 1932. (Pp. xxiv + 447; 263 figures. 18s. net.)

[5] *Questions cliniques d'actualité: leçons professées à la Clinique-service du Professeur Sergent, 2e série*. Paris: Masson et Cie. 1932. (Pp. 302; 17 figures. 45 fr.)

of scepticism; he describes with full pathological details two cases clinically resembling miliary tuberculosis which were really miliary gummata and fibrosis of the lungs. The occurrence of high blood pressure in the subjects of congenital syphilis, who do not show any evidence of cardio-renal change but are anaemic, is the text of Dr. J. Génévrier's lecture. Two articles deal with appendicitis —Dr. Paul Jacquet's on the chronic form, and Professor Vignes's on its occurrence in connexion with pregnancy. Professor Pasteur Vallery-Radot writes on specific hypersensitiveness, and Dr. L. de Gennes on anaphylaxis. In his clinical account of mongolism Dr. Turpin prefers this name to mongoloid or mongolian idiocy. The primary tumours of the adrenals are classified clinically in four categories by Professor Langeron of Lille: those with abdominal, those with metastatic, those with endocrine, and those with hypertensive symptoms. Professor Langeron recognizes paroxysmal hypertension with paragangliomas and continuous raised blood pressure, usually with cortical hypernephromas. Professor Gustave Roussy writes with authority on the present direction in which researches on cancer are taking; Dr. Henri Janet on the prophylaxis of diphtheria; and Professor Fiessinger on the incomplete or fruste forms of amoebic abscess of the liver.

Notes on Books

The work of Dr. WENDELL PHILLIPS on behalf of the deaf entitles his contribution, *Your Hearing—How to Preserve and Aid it*,[6] to the Appleton Popular Health Series to special consideration. As founder of the American Federation of Organizations for the Hard of Hearing, he writes with knowledge and sympathy of the problems that confront the deaf. In attempting to achieve the *via media* the authors have produced a book that is perhaps a little too popular for the medical man and too long and technical for the general public. The sections on the anatomy of the ear, the physiology of hearing, the prevention of deafness, and the indications for lip reading contain sound instruction and are well written. Some other parts which have been written in the American vernacular make tedious reading, although the advice given, for instance, in "Shall they marry?" is excellent. The book may be recommended for study by deaf persons and those who are in any way responsible for the welfare of the deaf, whether adults or children, because special attention is directed to social as well as to purely technical problems.

Dr. A. C. DOUGLAS has written a carefully thought out monograph on the physical basis of mind.[7] The aim of this work is to show that by taking full advantage of the latest advances in physiological knowledge the gaps left by associationism may be filled and the criticisms of gestaltism may be met, and a complete scientific theory of mind may be presented upon the materialistic basis which, the writer believes, behaviourism rightly demands. The book is excellently illustrated, and it includes a clearly written outline of the evolution and mechanisms of the nervous system. The author attaches much importance to the conditioned reflex, but some of his readers may find it difficult to agree with his view that the manifestations with which the psychopathologist is concerned will be found susceptible of a simple and rational explanation as the results of the interplay of cortical stimulations and inhibitions.

Dr. SANSOME and Mr. PHILP of the staff of the John Innes Horticultural Institute have contributed a volume on plant genetics[8] to the "Recent Advances" series published by Churchill. There was great room for such a book; for genetics, and particularly plant genetics, is one of the most rapidly developing of sciences, and so rapid has progress been that it is difficult for any but a few professional students to keep in touch with the literature. This book attempts to review and to discuss the recent developments of the chromosome theory of heredity that have occurred within the last ten years. It does not restrict itself entirely to plants, for no book on genetics can exclude the fruit-fly, Drosophila. It is addressed primarily to the teacher of genetics, to the researcher in genetics, and to the general biologist. Most excellent accounts are given of the origin of polyploidy, of auto- and allo-polyploids, of euploids and aneuploids, of structural hybrids, and of interspecific hybridization. A very good contribution to the species problem brings the book to an end. There is an adequate bibliography and an excellent index. The book is well written, well arranged, well illustrated, and admirably produced.

[6] *Your Hearing—How to Preserve and Aid it.* By Wendell Christopher Phillips, M.D., and Hugh Grant Rowell, M.D. New York and London: D. Appleton and Co. 1932. (Pp. 232. 6s. net.)

[7] *The Physical Mechanism of the Human Mind.* By A. C. Douglas, M.B., Ch.B. Edinburgh: E. and S. Livingstone. 1932. (Pp. xiv + 251; 24 figures. 15s. net; postage 6d.)

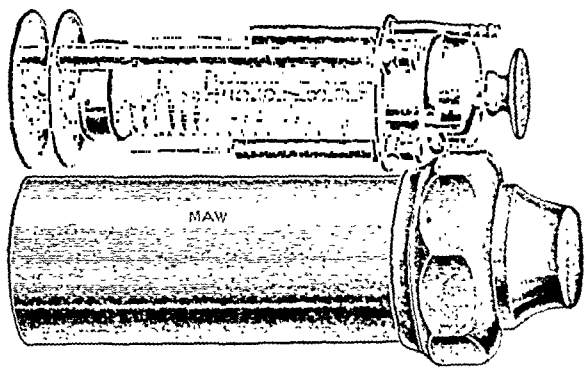
[8] *Recent Advances in Plant Genetics.* By F. W. Sansome, Ph.D., F.L.S., F.R.S.E., and J. Philp, B.Sc., F.L.S. Foreword by Sir Daniel Hall, K.C.B., M.A., LL.D., D.Sc., F.R.S. London: J. and A. Churchill. 1932. (Pp. x + 414; 56 figures. 15s.)

Preparations and Appliances

A SYRINGE CASE

Dr. W. R. THROWER (Weymouth) writes:

All physicians know the difficulty in transporting a 10 c.cm. syringe and needles in a sterile condition without damage either to the barrel or to the needle-points. To overcome this trouble I have had made a cylindrical metal case, 1⅜ inches in diameter and 5 inches long, with a spirit-proof screw cap. Into this case slides an accurately fitting metal



frame, which is so constructed that a 10 c.cm. syringe will rest vertically in the centre, while arranged round are four small tubes to contain needles of any gauge, and up to 4 inches in length. The case is kept full of spirit, which bathes the syringe and needles, so that they are ready for instant use when carried in the bag, whether for giving intravenous medication or for exploring a chest or other organ. All that has to be done is to pull out the frame by its handle, when the contents are easily accessible.

The instrument has been made for me on several occasions by Messrs. Maw and Sons, London, E.C.1, and stands up to use very well.

PARENTERAL CALCIUM

"Azoule" calcium L-B (calcium lactobionate solution) is prepared by Messrs. Allen and Hanburys Ltd. for the parenteral injection of calcium in cases in which oral administration is ineffective. "Azoule" calcium L-B contains 2 grams (31 grains) of calcium lactobionate—that is, approximately 0.1 gram of calcium, or the equivalent of 0.3 gram (5 grains) of calcium chloride, in each 5 c.cm. ampoule. The dose recommended for injection into adults is about 5 c.cm. daily, on alternate days, or every third day. Children should receive 1 to 2.5 c.cm. at the same intervals. Intramuscular and subcutaneous injections are preferable. Intravenous injection of any calcium salt should be used only in urgent cases, as it is apt to produce a digitalis-like effect, or even venous thrombosis.

RINGWORM DIAGNOSIS LAMP

The British Hanovia Quartz Lamp Co. Ltd. (Slough, Bucks) announces the production of a new portable diagnosis lamp for use in suspected cases of ringworm, and also in the diagnosis of eczema, pityriasis, erythrasma, psoriasis, and *x*-ray dermatitis. The apparatus, which provides a fluorescence beam of ultra-violet light that can be turned in any direction, is neatly finished, and available in three models (from £20) for use with alternating, direct, or either type of current.

THE DEVELOPMENT OF POST-GRADUATE MEDICAL EDUCATION

BY

HAROLD BALME, M.D., F.R.C.S.

FORMER DEAN OF THE SCHOOL OF MEDICINE, CHEELOO UNIVERSITY, CHINA

The announcement recently made in the *British Medical Journal* that the Government intends to proceed with the project for establishing a post-graduate medical school in London will give pleasure to all who have followed this proposition with hopeful expectation. The possibility that London, with its unrivalled clinical facilities, may soon possess an adequately financed and well-equipped post-graduate school is indeed a fascinating one, though much will necessarily depend on the methods which are employed in its organization and the degree of support which it receives from the profession. It must be admitted that, in spite of the incessant and devoted efforts which have been made in various quarters—notably those connected with the West London and Prince of Wales's Hospitals, and with the Fellowship of Medicine—but little has yet been done in London to study the needs of the graduate as an individual and separate factor in medical education, and the result has been that present facilities for this important branch of training lag far behind those of many other cities, especially in America and on the Continent.

A somewhat extensive experience of post-graduate study in London and the Provinces, carried on during a series of furloughs from service abroad, and culminating in a whole year recently devoted to this pursuit, has given me certain very definite impressions, both of the defects in our present system, and of the requirements which are, in my opinion, essential to the success of the new project, and these I venture to submit for consideration and criticism.

DEFECTS IN OUR PRESENT SYSTEM

Lack of Study Directed to the Peculiar Needs of Graduate Students.—To my mind the outstanding defect of our present system lies in the fact that, with a few honourable exceptions, the graduate is usually treated far more as a rather embarrassing accretion to the problem of medical education than as a completely separate entity, demanding separate study and separate facilities. The post-graduate student arrives at a hospital in which a lecture or class has been advertised, and almost at once feels out of place. He is "neither fish, nor flesh, nor good red herring." He is obviously not a member of the staff, nor of the student body, if the hospital possesses one. He is not even a regular clinical assistant, and he looks round somewhat furtively for a room where he can sit whilst awaiting the class. Nor does his discomfort necessarily cease when the hour for the lecture arrives. I remember at least one occasion when more than twenty of us who were attending an advertised post-graduate course waited over half an hour for a lecturer who neither turned up nor telephoned to say that he could not do so. This is admittedly an exceptional case, but what was not exceptional was to listen to lectures bearing little or no trace of preparation for the type of audience to which they were addressed. There were some which were of immense value, and had obviously been specially prepared for men and women who had already had experience of medical practice, but far too many lectures were little more than a re-hash of addresses given to entirely different audiences, whilst many others were far better suited to undergraduate students. (I write from an experience of five years ago, and conditions may have greatly improved in this respect to-day.) The impression which was left upon the mind of most of us was that, in spite of the numerous classes advertised in London for the benefit of post-graduate students, there were but few lecturers who treated the class with sufficient seriousness to spend any considerable amount of time in studying their needs, and making adequate preparation for their instruction. And yet it must be self-evident that a post-graduate class, consisting as it does of physicians who, for the most part, have already had considerable experience of professional work, demands an entirely different approach from the ordinary class of medical students, and will repay the most careful study and preparation.

Lack of Centralization.—Only those who have had actual experience of post-graduate study at a number of different London hospitals can form any conception of the aggravating amount of time and energy that is wasted every day in getting about from one lecture or class to another. There are admittedly certain valuable courses which are wholly conducted under one roof, but as a general rule the graduate will but rarely find his needs fully met in a single institution. Nor is this really to be wondered at. The larger and better-staffed medical centres in London are already so much occupied with the instruction demanded from them by their own under-graduate student body that they can hardly be expected to make large provision, in addition, for a class of men and women requiring a different method of instruction. The smaller hospitals, on the other hand, which welcome the post-graduate student, are, as a rule, too much crippled by lack of finance and by the demands of their clinical work to offer such wide facilities as will satisfy the post-graduate's varying needs. Thus it comes about that the unfortunate post-graduate student, in his endeavours to follow the most stimulating teachers and to attend what he considers the most valuable classes, finishes up by spending a large part of each day enjoying no other form of enlightenment than can be derived from the top of a London omnibus or from a study of the advertisements in the tube.

Paucity of Opportunity for Practical Work.—In dealing with the post-graduate problem it must never be forgotten that a large number of medical men and women who attend post-graduate classes are mainly concerned with the need for obtaining practical experience in those forms of medical and surgical investigation and treatment in which they feel themselves deficient. It is not so much lectures and demonstrations that they are seeking, as a chance of familiarizing themselves with certain methods of medical technique of which they are either ignorant or insufficiently experienced. Here a real difficulty is at once met, for but few of the existing hospitals are so organized as to supply this need, most of them naturally reserving such opportunities as they possess for their own student body, or for regularly appointed assistants. Some men of my acquaintance have endeavoured to solve this problem by going to the length of relinquishing for a time their own professional duties and taking modest posts as house-surgeons or clinical assistants. But such a solution can hardly be described as an ideal one, as it necessarily entails the expenditure of a large amount of time in ordinary routine duties which might far more profitably have been spent in other ways.

ESSENTIAL REQUIREMENTS FOR POST-GRADUATE EDUCATION

It will thus be seen that, in spite of the increasing opportunities which are open to post-graduate students in a city such as London, the present system leaves much to be desired, and it is therefore worthy of the most serious consideration as to what are the requirements that ought, if possible, to be met in establishing an adequate and successful post-graduate centre.

1. *The Centre Must be Primarily Educative*

One of the greatest difficulties which face all medical educationists lies in the fact that the hospitals attached to our medical schools are almost bound to take precedence in public interest and support over the schools themselves, so that the educational features of the institution are apt to be subordinated to the practical and clinical side. When we think of the great medical schools in a city like London we inevitably regard them in terms of the hospital which has given them their name and prestige. It is not so much the illustrious teachers, *qua* teachers, whom we recall, as the renowned physicians and scientists, the skilled operators, and the men who have

advanced the cause of medicine by their researches and experiments. Many of these men have been notoriously poor teachers and their lectures a mere weariness to the flesh, but their value to the institution in which they play so striking a part cannot possibly be overestimated.

In the organization of a post-graduate centre, however, the emphasis needs to be shifted elsewhere. The post-graduate student will but rarely be attracted by the glamour of a brilliant and spectacular operator, the renown of a popular physician, or the intricate technique of a famous pathologist. What he is seeking, first and foremost, is a competent, lucid, and inspiring teacher, one who will take interest in and understand the conditions under which his medical work has hitherto been carried out, whether it be in a busy industrial area, a rural community, or in service over-seas, and who will open up to him new fields of understanding and extend his sphere of practical usefulness. Such a teacher must necessarily be *au courant* with the latest methods of investigation and treatment, but must be sufficiently young and detached to be able to devote considerable time and thought to the problems of the post-graduate student, in a way that the busy London physician and surgeon, occupied already with the claims of a large practice, and very probably the demands of other hospitals, can hardly hope to do.

If this assumption is correct it would follow that the staff of such an institution should be selected primarily by virtue of their proved capacity as teachers, and it is worthy of consideration whether they should not be, in the main, chosen from the younger members of the profession, and engaged on short-term appointments for a limited period of years. This would not hinder the re-election of a successful teacher, but it would prevent the loss of freshness and stimulus which invariably takes place when a teaching staff becomes so immersed in clinical duties as to cease to be inspiring educators.

2. *The Centre must Provide for Very Diverse Needs*

It is only necessary to visit such well-known post-graduate centres as Vienna and New York to gain an idea of the extraordinarily diverse character of the medical men and women who take advantage of such an opportunity of further training. And if a post-graduate centre is to be the success which all its supporters ardently desire, each of these separate types must be studied individually and be separately provided for. To name but a few of them:

First, there is the practitioner who is keen to keep abreast of the times, but is conscious of having become "rusty." Possibly he has been engaged in a large and somewhat remote practice, in which every ounce of energy has had to be expended on the routine demands of his numerous patients, leaving little or no time to do anything more than glance at a weekly medical journal. Or, again, he may be returning to this country after some years spent abroad, where he has been forced by circumstances to live to a large extent on his own medical capital. In either event, the practitioner is now ready and eager to devote several consecutive weeks, or even months, to the endeavour to brush himself up in every branch of the subject, particularly those in which his practice mainly lies, or in which he has specially realized his deficiencies. It is for such a man that "refresher courses" are so invaluable, particularly when conducted by a picked group of stimulating instructors who will give the student the opportunity of seeing and practising for himself the newest methods of investigation and treatment, with which he is unfamiliar.

Secondly, there is the practitioner who has the opportunity of a far more limited period of study—possibly only a single day a week, or a complete fortnight such as is now offered to panel doctors under the national insurance scheme—and is anxious to use it in intensive study along a single line in which he feels that he could extend his field of service. Perhaps he is running the *x*-ray plant of a local hospital, and wants to see something of the newer methods of electrotherapeutics, such as might with advantage be introduced there. Or it is some particular technique with which he wants to be more familiar—for example, cystoscopy, spinal anaesthesia, blood grouping and blood transfusion, artificial pneumothorax, the injection of varicose veins and haemorrhoids, etc.—and he is anxious for an opportunity of carrying out such procedures himself under expert guidance and supervision. Or it may be that he has never felt at home in one or other of the special departments—dermatology, ophthalmology, ear, nose, and throat diseases, etc.—and he wants to seize the chance of some concentrated study in that particular line of work.

Thirdly, there are the foreign and colonial graduates, who, having completed their medical course in their own country, are anxious to widen their experience before starting upon their separate careers. They come from centres, it may be, where laboratory tradition is particularly strong, and are attracted to London by virtue of its reputation as a great centre of clinical teaching. What they are particularly seeking is the opportunity of attending out-patient clinics and ward rounds in the company of stimulating teachers, and of studying methods of diagnosis and treatment which differ in certain respects from those with which they are already familiar, and seeing types of disease not often met with in their own country.

Lastly, there is the young physician about to settle down in practice after holding various resident posts, and anxious to brush up in certain departments of medical work in which he has not had much opportunity of becoming experienced since his undergraduate days. He realizes that, as a student, with the overwhelming demands of his finals overshadowing everything else, he only devoted a minimum of time to certain types of disease commonly met with in general practice, and that it would be well worth while putting in a little intensive work along these lines before he makes his final plunge into practice or takes up a particular appointment in which special knowledge and experience will be expected from him.

If all these needs are to be met a large number of courses must necessarily be offered simultaneously all the year round, and a glance at such a syllabus as that which is published by the Post-Graduate School of New York will serve to show how numerous and varied these courses must be.

3. *The Centre must Offer a Real Home to the Post-Graduate Student*

A well-organized post-graduate centre must be far more than a mere place of call, providing specified courses at certain fixed hours. It should aim to be a real home of graduate medicine, offering facilities for the students' leisure hours as well as for the time he is under instruction. With this in view, comfortable common rooms and reading rooms, a well-stocked library, and a well-organized and self-explanatory museum should be regarded as essential parts of the scheme, in addition to well-equipped laboratories in which both research problems and the routine pathological work of the hospital are regularly carried out, and where there will always be a spare bench for any post-graduate student anxious to avail himself of the opportunity.

An inquiry office or bureau would also be of immense practical value, supplying students with information, not only on courses of instruction, scientific lectures, or surgical operations, but also on such practical matters as hotel and boarding-house accommodation, vacant medical appointments, practices offered for sale, and some of the many problems constantly met with by the practitioner. And perhaps it might not even be beneath the dignity of such a bureau to interest itself still further in the students' need of relaxation by supplying information on such topics as the nearest golf course and the best places of entertainment!

Given such a scheme, wisely planned and sympathetically carried out, the success of the post-graduate centre should be assured, and the encouraging results which have already followed the comparatively modest efforts recently attempted at various medical schools should justify the most optimistic forecasts as to the response which the scheme may hope to receive from members of the profession in all parts of the world.

SATURDAY, JANUARY 21st, 1933

A PUBLIC HEALTH STOCK-TAKING

While in matters of government a static policy may doubtless be pursued with a degree of success under suitable conditions, the same line of action in the field of public health would be looked upon nowadays by those conversant with the subject as doomed to failure from the outset, even if capable of being put into operation at all. It is recognized that the aim of the sanitarian is to promote the best health interests of the people. His policy, therefore, should be kinematic, not static; for he must, in the common phrase, move with the times, following hard on the heels of scientific discovery or setting his course along new channels opened by fresh conceptions of social responsibility or enlarged administrative ideals. But in all this he should not be content to drift passively on the stream of progress. It is not enough to be kinematic; he must be kinetic as well—a force to stimulate movement. And for his guidance in choosing the direction along which his kinetic energies may be applied he will do well on occasion to review his past achievements, mark his present position, and formulate plans for the future. Otherwise he may miss the opportunities which science or legislation hold out.

There has been a disposition in some quarters lately to hint that too often a lag of performance on opportunity exists in the public health services of this country, and the attention of authorities has been directed to the usefulness of periodical surveys of the work on which they are engaged. Such a survey is a kind of stocktaking, which makes it possible to evaluate results and, where necessary, to devise appropriate action. It may be of interest in this connexion to note some points in a large-scale public health inquiry reported from across the Atlantic. Alike in its parallelism and its differences as compared with the position existing in England, it has informative value. On May 1st, 1930, Mr. Franklin D. Roosevelt, Governor of New York State, appointed a Commission of fourteen members, under the chairmanship of Dr. Livingston Farrand, president of Cornell University, to take into consideration the activities of State and local health authorities in New York State, and to examine critically the extent to which the health needs of the people were being met. The final report of the Commission, now published,[1] presents its views and recommendations to the Governor.

Since public health problems are never wholly local, the Commissioners consider that State aid to local authorities is essential, particularly for rural areas and in the development of new health activities. They hold that the treatment of the insane, birth, death, and marriage registration, water supply standards, and rivers pollution prevention should as hitherto be administered by the State direct. For public health in general they animadvert upon the inefficacy of the existing small local authorities in villages and towns. They recommend that these should be superseded and that the county be made the unit. Cities with a population above 50,000 should have the option of remaining autonomous under a joint board. In counties above 30,000 of population the medical officer of health, who is styled health commissioner, should give whole-time service. The qualifications now prescribed for medical officers of health in New York State range from the degree of doctor of public health of an institution recognized by the University of the State of New York down to a correspondence course in public health of one year's duration, including at least one week of practical work, or an eight weeks' course in public health, including twenty attendances at an educational institution. The Commissioners regard these minimum requirements as quite inadequate, and recommend the establishment of two grades of qualification—namely, Grade I, for whole-time medical officers, involving an approved course of two scholastic years, together with one year of practical work or equivalent training; and Grade II, for part-time medical officers, involving three months of resident instruction in public health, or a correspondence course of one year with six weeks' resident instruction or equivalent training. In areas having a population under 5,000 the above requirements may be waived. Qualifications are proposed also for public health nurses, pathologists, laboratory officers, physicians in charge of sanatoriums, water superintendents, and other officials of health authorities.

The Commissioners advise the better co-ordination of school nursing with the general nursing services of the State. They urge the broadening and completion of the existing State tuberculosis scheme, and express the view that the use of B.C.G. is undesirable except under carefully controlled conditions. In the section dealing with venereal diseases reference is made to a one-day census of cases in medical practice and in clinics and in institutions throughout the State of New York in May, 1927, and again in May, 1930. In the former year the incidence of syphilis emerged as 2.35 per 1,000 of popu'ation; in the latter 2.72. Under maternity and child welfare it is noted that puerperal septicaemia in New York State, as elsewhere, accounts for one-third of all maternal deaths, and that albuminuria and convulsions come next in order and are followed by puerperal haemorrhage and other accidents of labour. The Commissioners draw from these data the somewhat defeatist conclusion that the great bulk of maternal deaths are due to causes which develop during or following labour, and that consequently prenatal hygiene alone will have no direct influence on many such deaths. As the number of births attended by midwives in the State is negligible they conclude

[1] *Public Health in New York State.* Report of the New York State Health Commission to His Excellency the Hon Franklin D. Roosevelt, Governor of the State of New York. State of New York, Department of Health, Albany, 1932. (Pp. 504; illustrated.)

that in the State medical care is the most important factor in maternal mortality, and with a view to the improvement of medical training recommend a minimum of fifty cases of labour for students of medicine. They advise, further, an intensive study, for at least one year, of every maternal death in the State, following in this particular, up to a point, the practice of this country. Under school hygiene their opinion is that the present system of annual inspections should be replaced by more thorough examinations at longer intervals. In the matter of mental hygiene the State Department operates for its purposes in all areas, and a certain amount of work is carried on by local authorities also. Closer co-ordination and full use of existing facilities are recommended.

As regards infectious disease, the decline of the typhoid fever death rate from 32.1 per 100,000 in 1900 to 1.6 in 1930 is ascribed to the chlorination of water supplies, the pasteurization of milk, and the better control of cases and carriers. The recession of the measles death rate from 13.5 to 1.4 in the same period is traced to such causes as the reduction of overcrowding, aided by the use of convalescent serum. In the course of the five-year toxin-antitoxin campaign from 1900 to 1930 756,073 persons, mostly young children, underwent prophylaxis against diphtheria. The extinction of diphtheria anticipated by some was not realized by this pioneer effort, but the case rate declined by 66 per cent., and 25 per cent. of all children in the State under 5 years of age are believed to have been rendered proof against the disease. It is estimated that for adequate community protection 35 per cent. of the children of this age group must be immune. The outbreak of poliomyelitis in 1931, amounting to over 6,000 cases, was the most extensive since 1916. Immune serum was obtained from some 1,200 convalescent donors, and 65 per cent. of cases had serum treatment: 60 per cent. were diagnosed in the preparalytic stage, and methods ordinarily available only in hospital were placed at the disposal of the practising doctor in the home. Milk-borne typhoid and paratyphoid fevers are apparently declining in New York State, while milk-borne undulant fever is increasing. The milk consumption in the State is 0.85 pint per person per day. Milk sold in the cities is safer and better than that in rural communities. Of city milk, 94 per cent. is pasteurized. The Commissioners consider that proper pasteurization has proved the greatest single public safeguard against milk-borne infection. The general question of medical care, including hospitals and home treatment, is rather lightly handled. Under the law any citizen in a county in need of hospital treatment is entitled to admission to a county hospital, at such charges as his means permit or without charge if he is unable to pay. Medical care at home is similarly authorized for those who cannot provide it for themselves. Recipients suffer no stigma of pauperism, but the full measure of medical service empowered by Statute has not yet been made generally available. The Commissioners pass from the topic with the suggestion that a legislative commission be appointed to study and make recommendations concerning medical care in New York State.

Dealing as it does with a great community which enjoys a merited reputation for progress, this report may serve as a model for those who have occasion to take stock of the position of similar health activities. While its recommendations necessarily relate more immediately to American conditions, its motives, form, and underlying principles are of general interest and application. Effective public health administration draws its strength from various sources, but it is largely founded on scientific progress and competent legislation, the facilities offered by both of which the kinetic administrator will desire to turn to account, for the benefit of the people under his charge, with the least possible delay.

DISEASES IN SEQUENCE

The occurrence of one definite disorder after another may be nothing more than a coincidence, but it is always tempting to assume some aetiological connexion and to argue from this about the fundamental pathology of one or both diseases. In the current issue of the *Archives of Disease in Childhood*[1] three papers deal with this type of association of two maladies, and in each instance the authors seek to find some causal relation. Dr. Alan Moncrieff describes two children in whom excessive obesity followed an attack of chorea. He argues that there is the possibility of inflammatory lesions in the central nervous system being responsible for both disorders, since obesity is known to follow changes in the region of the pituitary body and adjacent parts of the brain, and obesity has also been described as occurring in many instances after epidemic encephalitis, and after post-vaccinal encephalitis, cerebral tumour, hydrocephalus, polio-encephalitis, chronic meningitis, and cerebral trauma. The theory that prolonged rest in bed and lack of exercise is the cause of obesity in such cases is dismissed on the ground that the adipose changes did not occur during prolonged stay in a convalescent home, but only when, the disease process being over, the children returned to ordinary life. Other such cases have been described in the literature cited in Dr. Moncrieff's paper; in one patient under observation by Coburn the weight went from 88 lb. to 166 lb. during the few months after recovery from chorea.

The second sequence of diseases is seen in a case described by Dr. Frances Braid of osseous dystrophy following icterus gravis neonatorum. It is only within recent years, largely due to Hampson's life-saving suggestion of maternal serum or whole blood in the treatment of this serious type of jaundice, that patients have survived long enough for sequelae to be observed. The subsequent profound disturbance of the nervous system in some of these cases is a very interesting

[1] *Archives of Disease in Childhood*. Vol. vii, No. 42, December, 1932. London: British Medical Association House. (Yearly subscription (six numbers), 25s.; single number, 4s. 6d.)

observation, which, taken in conjunction with the syndrome described by Kinnier Wilson of progressive lenticular degeneration and cirrhosis of the liver, illustrates the close relation between hepatic function and the nervous system. In Dr. Braid's patient a curious cystic condition of the shafts of all the long bones was found one year after the jaundice had been successfully treated, and she quotes work on experimentally jaundiced puppies in which similar bone changes were discovered. It seems likely, in Dr. Braid's opinion, that the liver has some concern with calcium metabolism, and therefore with the normal growth of bone and nerve tissue, and it may be that this comes about because the liver is the main storehouse of vitamins and presumably controls their optimum distribution and activity. Another patient under Dr. Braid's care also developed bone changes after recovering from icterus gravis neonatorum, and here osteoporosis and a spontaneous fracture occurred.

The third example of sequence of diseases is also concerned with bony disorders following upon disease of another organ. Drs. E. A. Cockayne and F. P. Lee Lander note the occurrence of rickets following an attack of acute nephritis. This is particularly interesting in view of the comparatively rare condition of so-called renal rickets, in which evidence of previous inflammation of the kidneys is usually lacking. In the patient whose case is described acute nephritis developed in March, 1928; in April and the following months the subacute phase of the disease set in; genu valgum appeared in September, 1931, when the kidney disease had reached the chronic phase; and death occurred from uraemia in November, 1931, when the boy was aged 13, about three and a half years after the initial attack. *X*-ray examination showed typical rickety changes at the knee- and wrist-joints, and at necropsy it was confirmed that these changes were those of true rickets. Blood examination in the last stage of the disease showed that calcium was reduced to 7.5 mg. per cent., and phosphates increased to 9.8 mg. per cent. The kidney changes were proved on histological examination to be those of chronic glomerulo-tubular nephritis.

AN EXAMPLE FROM NEW YORK

An interesting announcement comes from New York City. It appears that the sanitary code of that city requires a medical examination to be made before any person can obtain a permit, issued each year from the Department of Health, to engage in any occupation which involves the handling of food; and that there are some 325,000 such "food-handlers." The purpose is, of course, to prevent the handling of food by those who suffer from some communicable disease, though it is not stated what procedure is to be adopted should such a disease be acquired during the year. Possibly this is stated on the permit, and appropriate action made a condition of its issue. Hitherto most of these medical examinations have been made at special clinics established by the Department of Health, but as from the beginning of the present year the applicant is to be examined by the private practitioner of his choice, who must fill in the application as regards the relevant health history and condition. This application is forwarded to the appropriate division of the Department, and the permit for the current year is sent to the examining practitioner, who, in turn, hands it to his patient. The fee is a private matter between doctor and patient. The reasons for making this change are stated to be "the conviction that the State should not compete with private physicians in the practice of medicine, together with the precarious economic position now occupied by a large part of the private physicians." The Health Commissioner, though he thinks that the service could not have been so successfully established otherwise than as a definite department of health activity by the city, is of opinion that, when the machinery is moving smoothly, so long as the private physician is willing and able to render any required service, it is unfair to do the work at the expense of all the taxpayers. The new arrangements for the medical certification of "food-handlers" will not only result in a definite saving to the city, but there will be a further important effect. "For years," says the Commissioner, "we have been endeavouring to interest the medical profession more and more in public health work, feeling that each physician in the city should really be a health officer in all that the word implies. With the full co-operation of the medical profession in this work we shall undoubtedly pave the way for their help in connexion with other services now being offered by the Department." Similar conditions with regard to public expenditure and the position of practitioners obtain in this country, and the same considerations are applicable. It may be suggested that there are some health services here to which it would be advantageous for the Ministry of Health and local authorities to begin to apply the principles and methods just made operative in this instance in New York.

DIURETICS

The introduction in recent years of certain new diuretic drugs has greatly extended the scope of therapeutics in this direction. Lately, the effects of the intramuscular injection of bismuth sodium tartrate have been studied by Stockton, and the results recorded in the *Archives of Internal Medicine* (1932, 1, 142). Miller and Feldman[1] have also reported on the uses of massive doses of urea as a diuretic over prolonged periods. Mercury was the first heavy metal to be used in organic combination as a diuretic, in the form of novasurol. Its application was, however, too likely to produce dangerous toxic results. Salyrgan proved to be just as good and less toxic. Its best results are only obtained by intravenous administration, while intramuscular injection, although quite effective, may cause local necrosis. The bismuth salt would appear to have certain advantages, in that it is safe and effective when given intramuscularly. The diuretic action of the drug is less sudden than that of the mercurial preparations, but more prolonged. The total increase in urinary excretion is equally good in the case of the bismuth salt. It would appear that there is a certain common mode

[1] *Arch. Int. Med.*, 1932, xlix, 464

of action in these salts of the heavy metals, which is also shared by other diuretics of the xanthine group, such as theocin, theophyllin, and theophyllin-ethylene-diamine (euphyllin). The effect of their administration is to mobilize the salt in the tissues of the body and bring it into the blood stream. The sodium chloride content of the plasma has been examined before and after the administration of these drugs, and an increase is found to occur in every case in which diuresis is caused. As a result there is an increase in the chloride output in the urine. No changes of any importance were observed in the level of the urea in the blood, but the output of urea in the urine was increased. In the cases with oedema the chloride content of the plasma was constantly found to be lower than normal before the diuretic was administered. The level of urea in the tissues and in the blood is kept so uniform that any influence of this substance in promoting diuresis could not be demonstrated. The use of massive doses of urea as a diuretic has long been known. Miller and Feldman gave 10 to 25 grams (2.5 to 6 drachms) thrice daily; a 40 per cent. aqueous solution was used, with fruit juice to cover the unpleasant taste. When about 50 grams were given daily most of the patients soon lost their oedema. The administration of urea was continued for months if there was any tendency for the oedema to return when the dose was diminished or the drug discontinued. It is surprising that some cases regained their cardiac efficiency on urea alone without the use of digitalis. Urea did not appear to lose its effect during a long administration. In one case examined at necropsy no damage had resulted to the kidney. In many cases of congestive heart failure the blood urea rises and the power of the kidneys to concentrate is diminished. Here it is unlikely that the drug will be effective, for the kidneys cannot respond to the already heightened level of urea in the plasma. In none of the cases studied was the blood urea increased. It seems probable that the administration of urea in large doses may be useful in dealing with some cases of resistant cardiac dropsy, though for the most part, when the kidneys are capable of acting, oedema can usually be got rid of by the drugs already in use.

AN ANTIMALARIAL FISH

Dr. O. Trausmiller, director of parasitology in the School of Hygiene at Zagreb, in Yugoslavia, recounts[1] his success in getting rid of malaria in two small islands in the Adriatic, cheaply and effectively, with *Gambusia holbrooki*, an American fish that preys on mosquito larvae. The larger island (Veglia in the maps, now called Krk), of 26,000 inhabitants, is of a chalk formation, so fissured that falling rain at once disappears. Apart from rain, there is no water on the island except in underground cisterns (fed from the roofs) and in pools with impermeable bottoms. These last are small, shallow, often filthy, with much weedy vegetation, and fouled by cattle. In them only are found anopheles larvae and pupae. In 1924 two hundred gambusia were introduced. The climate suited them, they bred rapidly, spread obstinately, and by 1926 had firmly established themselves. At first, while the fish were few, the vegetation in the ponds was kept down, but that seems unnecessary. Prophylactic quinine was now reduced. Nevertheless, malaria decreased, and the spleen index (children) fell from 19 to 2 in many villages. The other adjacent island Pag (Pago) is smaller, with 10,000 inhabitants. Its uplands are similar to those of Krk. In 1928-9 gambusia were introduced into a large brackish lake near the sea, and there they throve. It was speedily noticed that the mosquitos, which had been a source of great misery in the district, were being reduced, and, though the vegetation in the pools was uncontrolled, malaria diminished. It had been mostly benign tertian, but there was also some of the malignant and a little of the quartan variety. The spleen index of the community, formerly 59, fell to 39—mostly old, chronic cases. Mosquitos were no longer found in the houses, until the cold weather slowed down the activity of the gambusia. Since malaria persisted as before in the swampy fertile valleys of the south end of the island, not yet stocked with fish, the relief in the north was not due to climate. Dr. Trausmiller considers that gambusia, in suitable climates, diminish malaria till it becomes manageable and ceases to be of social importance. He insists on the debt owed to Sella, who brought from America to Europe gambusia, a "valuable, cheap, and automatic resource against malaria."

[1] *Arch. für. Schiffs- u. Tropen-Hygiene*, October, 1932.

ALCOHOL AND DRUG ADDICTION IN GERMANY

The efforts of successive German administrations in dealing with the national alcohol problem possess many interesting features. Dr. P. Wolff, editor of the *Deutsche medizinische Wochenschrift* and an active worker in this field under the League of Nations, recently explained to the Society for the Study of Inebriety the legislative and other measures which had come into force and those which were expected. The Licensed Premises Act, which was introduced in July, 1930, had as its chief object the prohibition of the sale of alcoholic refreshment to intoxicated persons and to young persons under 18. It also aimed at preventing the sale of tobacco to children under 16, the practice of charging corkage on meals taken without alcohol, and the sale of spirits on sports grounds. The measure contained a number of provisions which have been familiar in this country for many years, such as restriction of the granting of licences, and the fixing of opening and closing hours. Further, it provides for a measure which, though not in force in this country, might, according to some opinions, find a useful place—namely, the prohibition of the sale of spirits at certain times, such as pay days and election days. This legislation seems to fall in with the tendency of private habit, for the consumption of spirits in Germany has decreased to less than a quarter of what it was before the war, and that of beer to just over half. Chronic alcoholism is on the downward grade, and the form in which it is usually encountered is milder than hitherto. Delirium tremens, for instance, has become very infrequent, and the mortality from alcoholism in the hospitals is only about one-third of the pre-war figure. The cure of drunkenness in Germany is systematically organized on a national basis, and particular importance is attached

to treatment in the early stages of alcoholism. The new Penal Code contains provisions empowering judges to enforce a withdrawal cure and to subject the inebriate to supervision. The graduated treatment in use is considered to act as a deterrent to early drunkards. It is administered in about twenty public hospitals and a large number of private ones—some of which have "abstinence sanatoriums" as special departments—while there also exist State workhouses for incurable drunkards. The statistics quoted by Dr. Wolff show about 30 per cent. of successful treatments and 60 per cent. of failures. The most effective factor in reducing national drunkenness seems to have been the raising of the price of alcoholic liquors by taxation. Statistics of drug addiction, published in 1928, show a figure of between 4,000 and 6,000 addicts, including 500 doctors —about 1 per cent. There is as yet no legal restriction on the prescribing powers of medical addicts, but legislation for this purpose is soon to be introduced. In April, 1931, an ordinance was promulgated, with the co-operation of the medical profession, which seems to have effected a considerable lessening in drug addiction. Medical men may not prescribe opiates in bulk, and must register all prescriptions of more than 0.2 gram of morphine or 2 grams of opium daily. The profession is encouraging the use of substitute preparations, and of suppositories in place of injections. Since the introduction of this ordinance the consumption of morphine has gone down by 20 per cent. and that of opium by 30 per cent. Heroin, which plays such a large part in addiction in other countries, is unpopular in Germany, and the whole consumption per annum is only about 4 kilos. The consumption of cocaine, which also came under the ordinance, has decreased by more than 50 per cent., and the medical profession has largely discontinued its use. Pure cocaine is no longer supplied to doctors, modern substitutes being used whenever possible. The illegal drug traffic, according to Dr. Wolff's personal observations, has considerably diminished, and the authorities hope before very long to suppress the use of cocaine entirely.

HOSPITALS AND CHILD HEALTH

"Capital invested in hospitals in the United States is estimated at more than three billion dollars." This is the opening phrase of the introduction to a report[1] issued by the White House Conference on Child Health and Protection. The monetary standard seems at first sight rather crude and unfeeling. Yet it is a good working test. There should be some definite idea of the return on such an investment, which must be measured in terms of the effect on the health of the country. There are no fewer than 6,667 hospitals in the United States, with 905,246 beds. Of these those set apart for children number 81,055 and 47,939 cots, totalling 118,994, or some 13 per cent. of the grand total. If the children under 14 constitute one-fifth of the population, the allotted number of beds is not proportionate. The report suggests that this may be due to economic factors, or it may be the reaction of parents to hospitalization. In 1929 it was found that 69 per cent. of the beds were occupied. No hospital can be continuously full; there must be times for repairs, and there must be beds in reserve for epidemics. Nevertheless the view is expressed that it should be easily possible to run to 80 or even 85 per cent. of capacity. Such a large margin suggests that there has been too much building of hospitals; that it would be better to have fewer small hospitals of 50 and 100 beds, and more larger units. It is doubted if the smaller hospitals can afford the equipment necessary for the proper care of patients. The report gives a most elaborate and detailed account of an investigation into the whole of the work for the health of American children. This covers much more than hospital services as we should define them, for it links up with these all the work that is done in this country by or through the school medical services, voluntary aid associations, care committees, convalescent homes, nursing services, and the like. After a review of existing conditions the committee which prepared the report sets out its conclusions in a number of clear-cut recommendations. Briefly the findings are these: there is at present a lack of adequately trained personnel for positions in medical social work in the country. There is a pressing demand for better-trained workers. There are enough training centres, but the accommodation is insufficient. The true purposes and specific contributions of medical social service to medical practice are not generally understood. Co-operation between hospitals and community social agencies is hampered by lack of pertinent medical knowledge and discriminative use of medical facilities on the part of non-medical social workers. Lastly, there is failure to appreciate the strategic opportunity for inculcating good habits, based on sound principles of mental hygiene, by those who are responsible for the care of children in hospitals and dispensaries. Thus the charge, so often raised in our own country, that there is insufficient linkage between the social services and the purely medical services, has its counterpart in the United States. How to bring them together in a practical working arrangement, which will not cramp the free activities of either, is a problem difficult to solve.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement* and *Epitome* have been printed; they will, however, not be issued with all copies of the *Journal*, but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, B.M.A. House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly should intimate this.

The eighth annual address to newly qualified medical practitioners and senior students of the London hospitals, arranged by the Metropolitan Counties Branch of the British Medical Association, will be given at B.M.A. House, Tavistock Square, W.C., by Mr. Wilfred Trotter, F.R.S., on Tuesday, March 14th, at 5.30 p.m. The title of the address is "Emergency."

Nova et Vetera

INCIDENCE OF DENTAL DISEASES IN ANCIENT EGYPT

BY

DOUGLAS E. DERRY, M.B., CH.B.

PROFESSOR OF ANATOMY, EGYPTIAN UNIVERSITY, CAIRO

In the *Journal* of October 22nd, 1932, there is a short note of a communication made by Professor Elliot Smith to the Comparative Medicine Section at the Centenary Meeting of the British Medical Association on the condition of the teeth in ancient Egyptians. He says that after the influx of a large number of aliens in the third, fourth, and fifth dynasties, dental caries became so common "that more than 80 per cent. of the people had caries." Previous to this, he remarks, caries was rare, but alveolar abscesses due to the wearing down of the teeth, with subsequent exposure of the pulp cavity, were common. With this latter statement everyone who has examined skulls of the pre-dynastic period will agree, but the assertion that 80 per cent. of the people in the pyramid age suffered from dental caries is so incompatible with my experience that the following facts derived from skulls at present in my possession may be of interest.

In 129 skulls of people belonging to the Badarian and early pre-dynastic period, eighty-six of which are before me, I have found seven with carious cavities. In two of these the enamel was already worn away, so that they are not actually in the category of those which exhibit a cavity in unworn enamel, but even if we include these we only get 5.4 per cent. of carious teeth in the pre-dynastic people of the Nile valley.

Of the pyramid age, the fourth, fifth, and sixth dynasties, I only possess seventeen skulls. Of these, three exhibited carious cavities, in two of which, however, the teeth are so worn down that the cavities cannot be diagnosed with certainty as having been primarily affections of the enamel. The third case is definitely one of primary erosion in the enamel. These three skulls are all from graves at Sakkara, of the sixth dynasty. In this pyramid period, therefore, judging from the seventeen skulls before me, we have at the most 17.6 per cent. exhibiting caries. If, as I am inclined to believe, two of these are only secondary to wearing away of the enamel, then only one skull in seventeen shows primary caries; this reduces the percentage to about 5.9, which is practically the same as in the pre-dynastic period. Indeed, it is difficult in examining skulls of the two periods to see any difference whatever in the condition of the teeth. The vast majority of skulls obtained from cemeteries are, of course, those of people of advanced age, and in these the teeth are almost invariably very worn down, owing, as we believe, to fine particles of silica derived from the stones employed to grind the grain becoming intimately mixed with the flour. A very large proportion of these skulls show extensive infection through the exposed pulp cavity round the root of the tooth in the form of alveolar abscess cavities. I have not found one case in the eighty-six pre-dynastic skulls referred to in which, the person having died before the teeth had become sufficiently worn to expose the dentine, there is any sign of dental trouble.

In the above account I have described the condition of the teeth in crania of the fourth to sixth dynasties, as this is the period referred to by Professor Elliot Smith, but in skulls of the eleventh and twelfth dynasties, of which I possess twenty-one, mostly of the upper class, I have only one case—that of a young adult woman—in which there is a minute hole in the enamel of a lower molar. Had there been such extensive disease in the earlier dynasties it is difficult to see why it should have practically disappeared some six centuries later. Actually in the twelfth dynasty there appears to be about the same percentage of cases of caries as in both the pre-dynastic and pyramid periods.

We have been accustomed to say that not until the Ptolemaic-Roman period in Egypt, when diseases, or at least those which left their mark on bones, certainly became very much more frequent, did dental caries become common, but even this statement may need modification. At the present moment good teeth are the rule amongst the country people. Major A. G. Biggam, professor of clinical medicine in this university, who drew my attention to Professor Elliot Smith's note, expressed surprise that dental caries should have been so common in the pyramid age, as his experience with patients seen in hospital is that, while pyorrhoea is frequent, caries is not. At present we have no statistics as to the incidence of the disease to-day, but it is hoped to remedy this. Suffice it to say that, while there appears to be a large number of persons affected with dental caries in the town, the consensus of opinion, in the absence of statistics, is that the condition of the teeth in the general run of fellahin is excellent.

AN ELIZABETHAN DOCTOR'S WILL

Dr. F. William Cock, F.S.A., of Appledore, Kent, sends us the abstract printed below of a will of a country doctor of the time of Elizabeth.

This will (Dr. Cock writes) is interesting from several points of view. The testator, Henry Mylborne, evidently combined the "science" of a G.P. with the grocery trade. The Apothecaries' Company was not formed till more than forty years later. It then separated, by means of its charter, from the grocers and similar businesses. A survival of the combination of the two occupations was still going in my youth, as the "general" grocers' shops hereabouts dealt largely in drugs, whether innocuous or poisonous, especially in opium, which, in this then malarious district, was largely consumed by women when aguish. They would keep a thumbnail at the right length, and this filled from a bolus of gum opium was the proper dose—I suppose about a grain in weight.

Mylborne's will suggests that he was a bachelor with his sister keeping house for him, and that his brother was also a doctor, of whom he was not too fond. Note also that he speaks of his profession as his "science"—a rather early use of the word for a country apothecary of the time. Note also the "potecarye." Well into last century old-fashioned gentry did not say, "I sent for the doctor," but "I used the potecary." I fancy that "cheste" contained most of the valuables of Henry Mylborne, and he was determined that his sister alone should have it.

9. May 1575. Henry Mylborne of Tenterden (Kent) Surgeon

To the poore of Tenterden 13s 4d at day of my buriall. To my sister Elizabeth Mylborn my mare and my Coltes and twentie shillings and all other my howseholde stuffe whereof part is in my shoppe and parte in my bed chamber and all such p'cells of moneye as at the makyng hereof are dewe unto me for cures allredye cured. All suche legaces unto my sister (and) my keye of my chest with the cheste ytself & all thinges in yt conteyned. She shall patientlie enjoy ymediately after my decease W'hout any lett interruption or gainesaying of my ex'or or any other whosoever. . . . To my brother Edmonde Mylborne of Hasting all such Potticarye ware as I have in my shoppe wth my instruments, grosserye ware, spices, potts and all other thinges apperteyninge to my science, and tenne shillinges in consideration of his paynes in comyng downe & towards the charges of my buriall . . . if anything lacke he to fulfill at his owne costes. Whereof I give him all suche bookes as I have. He to be ex'or but if he refuse this then I revooke my former bequest to him & will the same to my sister Elizabeth who then to be sole ex'trix.

Proved 10. April 1576 (at Canterbury).

I owe the transcript of this to my friend Mr. A. H. Taylor of Canterbury.

PROBLEM OF THE OUT-PATIENT

THE PRINCE'S LETTER TO THE KING'S FUND

At a meeting of the General Council of King Edward's Hospital Fund for London, held on January 10th, the following message was read from the President, H.R.H. the Prince of Wales:

"The report of Lord Onslow's Committee on the out-patient question is now in your hands. Besides containing the committee's own conclusions and recommendations, it is a storehouse of information about the procedure at the hospitals, and also about the alternative and supplementary agencies for the treatment of patients suffering from minor ailments. This should be a great help to the hospitals. The question to be decided is how far the present time of waiting is unavoidable, how far it can be shortened by changes in procedure, and how far it is possible, without causing hardship, to reduce overcrowding by arranging for some of the less serious cases to be treated by general practitioners elsewhere. It should be much easier for the hospitals to decide this now that they have all this information before them, collected together in a handy form. The report will also enable the public to realize how difficult a problem it is, and how many experiments the hospitals themselves have been making to reduce the hours of waiting. The accumulated experience is now rendered available for study. But the report is more than a mere academic discussion of the question. It is meant to lead to action. Its actual recommendations are carefully worded so as to respect the freedom of the individual hospitals, which is an essential feature of the voluntary system. But the committee present a strong prima facie case for believing that part of the waiting time can be reduced, and they want the hospitals to study that case in detail with a view to taking action wherever it is practicable. To ensure that this is done, the report ends with the definite recommendation that the King's Fund should consider to what extent it can help to carry out the recommendations by making available the detailed information accumulated during the inquiry, and by such other methods as may be relevant. I reported this to the council on December 15th, and I am glad to say that the council unanimously agreed that it should be acted on at once.

"I have now appointed a small committee for this purpose, and the council have decided to give it the power not only to consider, in consultation with the hospitals, what steps can be taken, but also, in co-operation with the Management and Distribution Committees, to take the necessary steps. This will ensure that the report is not pigeon-holed, but is used as a practical guide to action, wherever action is found to be possible and desirable. This committee will be called the Out-patient Arrangements Committee, and I have appointed the following to be its members: Sir John Rose Bradford (chairman), Dame Rachel Crowdy, Sir Ernest Morris, Sir Isidore Salmon, Mr. Eric Pearce Gould, Lieut.-Colonel A. P. B. Irwin, and Mr. R. H. P. Orde. These have all done actual hospital work; some are experienced organizers in other departments of life; four of them were members of the original Out-patient Committee.

"I take this opportunity of expressing my personal thanks to Lord Onslow and the members of his committee for the great amount of care and attention they have given to this difficult subject, and for the way in which they have dealt with it. I trust that their work will prove fruitful for the benefit of the hospitals and of their patients. In conclusion, I offer you my very best wishes for the prosperity during 1933 both of the King's Fund and of the hospitals."

The General Council unanimously resolved to tender grateful thanks to His Royal Highness for this gracious message. It was further resolved that the report of the Out-patient Committee, 1932, be commended to the consideration of the hospitals and of all others concerned. The council placed on record its grateful thanks to the Earl of Onslow (chairman) and members of the committee (Sir John Rose Bradford, Sir Francis Fremantle, Dame Helen Gwynne-Vaughan, Sir George Macdonogh, Sir Ernest Morris, Mr. Orde, and Sir Isidore Salmon), who, by the information accumulated and the recommendations made in their most valuable report, had rendered a lasting service to the voluntary hospitals of London and their patients.

Resolutions providing for the work of the Fund for 1933 were adopted, including the following powers of the Out-patient Arrangements Committee: (*a*) To consider, in consultation with the hospitals, what steps it would be practicable and advisable for the King's Fund to take—(1) for assisting the hospitals in the study of the different methods of out-patient procedure indicated in the report of the Out-patient Committee, 1932; and (2) for promoting the development of out-patient organization in the directions suggested by the report. (*b*) To take such steps as the General Council or the Management Committee shall approve for either of the above purposes.

THE VALUE OF HEALTH

AN ADDRESS BY R. G. HOGARTH, C.B.E., F.R.C.S.

At the invitation of the Merseyside Hospitals Council, Mr. R. G. Hogarth of Nottingham, a past President of the British Medical Association, delivered on January 11th an address at St. George's Hall, Liverpool, on "The value of health." The address was of a popular character, and was intended to lead up to the advantages of the British Provident Association scheme of hospital insurance for the middle class.

Mr. Hogarth began by pointing out that the science of health, as the experts now understood it, was only in the process of being discovered, and this for the best of reasons, because it was only within the last hundred years that the medical profession had begun to be master of its own science and practice. No real progress in any branch of knowledge was possible until cause and effect had been firmly established, and no science of health could come about until medical science itself had been liberated from its old empiricism and set forward on its new career. In the old days—and not so long ago either—health and life were almost matters of luck or accident. The great killing epidemics recurred at intervals. Other diseases were permanently encamped in the midst of the community, as, indeed, they still were; but formerly they took an enormously higher toll, because the environment was then as favourable to their spread as it was now adverse.

It was not mere perversity or callousness on the part of the governing classes that prevented the establishment of a Ministry of Health in this country until the great war. To have established it very much earlier would have been impossible, because the grand and inspiring conception of a nation in health had not arisen. How, indeed, could it arise when the prevailing idea about diseases and epidemics was that they were inevitable—not merely allowed by Providence, but sent for punishment and for the good of the people? The present generation could scarcely have any conception of the opposition against which the early sanitary reformers, such as Chadwick, had to contend. It was sarcastically said of the British people that they would prefer to take their chance of cholera rather than be bullied into health. And Mr. Hogarth candidly admitted that if public opinion in those days was not ready for sanitary reform, general medical opinion was not very much more advanced.

NEED FOR HEALTH DISCIPLINE

The battle of sanitation had now been won, yet there remained, as in Victorian days, the lazy mind which did not want to see, the selfish mind which resented being convinced, and the bigoted mind which would not admit new evidence. There was still need to cultivate collective health sense. The development of such a sense in the general body of the nation would produce magnificent results, but it could not be said to exist so long as millions of people regarded the medicine bottle with superstitious

reverence, and thought that a panel doctor who did not prescribe it was no good. A greater discipline was needed —as a concession to a democratic age, let it be called self-discipline. The movement towards discipline had many disappointments—witness the painful lack of success of the campaign against litter in the streets and on the countryside—yet it had its victories, as, for instance, the disappearance of the disgusting habit of promiscuous spitting. This disappearance was due, no doubt, to the deep impression made on the public mind by the discovery that the habit conduced to the widespread diffusion of the tubercle bacillus ; but it was so complete that the hideous one-time article of domestic furniture, the spittoon, was now only with difficulty obtainable.

Perhaps, as an eminent professor had said, to secure the submission of the Anglo-Saxon to discipline the thing must be called by some other name, such as education. Never before in human experience had the health of the individual been so largely in his own hands to make or to mar. It was within his power consciously to hold the processes of decay in check, to oppose retarding forces, and retain the maximum maturity for a much longer time than ever before. A child born to-day had an expectation of life twenty years longer than his grandfather. If a man could not add to his stature by taking thought, he could by so doing add to his length of days. But mere survival was not enough ; the life so prolonged must be happy and active, not a valetudinarian existence.

TRIUMPHANT INVALIDS

Admittedly it was possible to overcome physical disability and live a full life in spite of it. Mr. Hogarth mentioned, for the encouragement of those of weakly physical endowment, some outstanding examples of triumph: Arnold Hills, the shipbuilder, who suffered from a crippling paralysis, but directed his great business with indomitable energy ; Lord Trent, better known as Sir Jesse Boot, who for the last few years of his life could hardly move a limb, and yet whose brain never ceased to plan a more perfect organization for the great business which he had founded ; and Lord Curzon, who worked tirelessly, although suffering throughout life from a painful weakness of the spine which would have killed ambition stone dead in most men. (Mr. Hogarth might have added another example in Mr. Franklin Roosevelt, President-Elect of the United States.) But the hard fact remained that these were the exceptions which proved the general rule that when health was broken a man's life was finished and his usefulness done.

In these days people thought too little about their own obligations to the State in respect of health, though they required no reminder of what they called the State's duty to them. If they were ill they demanded that the State should provide them with medical attention, and, if their case was serious, with a hospital bed, and that the larger share, if not the whole cost, should be met out of other pockets. Mr. Hogarth's own view was that, while it was the duty of the State to see that no one in his hour of need lacked medical attention, and that institutional treatment was available for those in extremity, nothing ought to release the individual from his personal duty to keep himself in health and contribute what he could to the cost of his medical treatment.

And what was health but a just balance, a timely co-ordination, a nice equipoise of functional activities? It related to mind as well as body. A sound body was of little value without a sound mind, which in its turn was largely dependent upon the maintenance of harmony in the body. One of the great hindrances to health was worry of mind, fretfulness, fear obsessions. Cheerfulness was a more precious ingredient in the making of health even than wisdom. If fear were cast out of the mind a surprising immunity would be gained ; and, equally, envy and hatred were not only ugly vices of the soul, but enemies of health.

THE DIET OF THE PEOPLE

Mr. Hogarth commended as a simple rule of life the maxim of the Greek philosopher: "Of nothing too much." The question of temperance brought him to the question of diet. Although the general standards of health and fitness were much higher to-day than a generation ago, it was astonishing how careless the majority still were in diet, and what complete lack of judgement was displayed by a multitude of women in the choice and preparation of food. The root cause, perhaps, was a growing distaste for the work of the kitchen. The food of the British people as it came to the table did not compare favourably with that of many other nations, although food was cheaper and more varied in this country than elsewhere. Professor Mellanby, whose work on the prevention of rickets was universally recognized, had declared that there were two main defects in English diet—namely, that it contained too little of such foods as milk, eggs, vegetables, cheese, and fish, and that it contained too much bread, rice, oatmeal, and other cereals. While many diseases were directly due to vitamin deficiencies, those same deficiencies made the individual less able to resist the onslaught of a whole range of infectious diseases, and weakened the defence against the attack of the parasites. It was not a question of expensive foods. There was no one in receipt of a living wage who could not afford the articles of diet just mentioned, and if they were prepared to take a little trouble they could all insist on good wholemeal bread instead of white bread, from which most of the natural goodness had already been extracted, while nearly all the fruits of the earth were now for their use throughout the year.

Finally, Mr. Hogarth spoke of the merits of the Merseyside hospitals contributory scheme, whereby the people of Liverpool and Birkenhead and other towns had linked themselves to their general hospitals, and made them their own in a sense which was not true before. He called special attention to the difficult position of the middle and professional classes in relation to hospitals. The number of pay beds or pay wards at the hospitals was inadequate to meet their needs, while the nursing home often meant a prohibitive cost. The British Provident Association had lately been remodelled with a view to this particular problem, its object being to secure a very large immediate increase of the accommodation available for the middle class in existing hospitals, either by building new wards or making new outside extensions which would be within the range of service of the hospital equipment. He looked forward to the time when the subscribing members of the British Provident Association, like those of the Hospital Saving Association, would be over a million strong.

OPHTHALMOLOGY IN THE ORIENT

TRACHOMA AND DIET

The sixth annual report of the Giza Memorial Ophthalmic Laboratory in Cairo[1] shows that the good work which has been done there, under the directorship of Dr. Rowland P. Wilson, is continuing. Among the several cases recorded are some of leprotic lesions of the eyeball. There is also an account of research into alleged vitamin deficiency as a cause of trachoma, from which disease 100 per cent. of the population of the villages in Egypt suffer, and 70 per cent. of the more prosperous classes. Keratomalacia, even in its milder manifestations, is extremely rare. While there is often a deficiency of vitamin D in the diet of the fellahin, it has been agreed that the general vitamin needs of the people are satisfactorily met. A commission has recently studied the dietary of these people, and reports that the fellahin in the oases are amply supplied with natural foods—eggs, fruits, and vegetables being abundant. There is no need to import any foods, except flour, tea, and sugar. Practically everything that is grown is consumed locally. In spite of this plentiful supply of nourishing foods, trachoma is as prevalent as in the ordinary villages of the country. It seems more unlikely that vitamin deficiency is specifically related to trachoma.

With regard to the relation between the trachoma of Egypt and that seen in America, Dr. Wilson, who has visited the United States, says that he examined several

[1] Sixth Annual Report of the Giza Memorial Ophthalmic Laboratory, Cairo. Schindler's Press, Cairo. 1932.

private patients (American subjects) diagnosed as suffering from trachoma. In these cases the disease differed so widely from Egyptian trachoma that one might quite well have been dealing with a different disease altogether. It was also observed that follicular conjunctivitis, often mistaken for trachoma, is much more prevalent in America than in Egypt. Professor Lindner of Vienna, who is one of the world's foremost trachomatologists, and who visited the United States in 1930, maintains that many of the cases of so-called trachoma in America are simply cases of follicular conjunctivitis, and that the bacterium which Noguchi discovered is only one of the causes of follicular conjunctivitis. Be this as it may, the real significance of *B. granulosis* is not yet known, but these facts may account for the failure so far to find this organism in Egypt. There is also a record of a careful piece of observation by Dr. Wilson into the character of the vessels at the corneal limbus in normal eyes and in early trachoma. It is suggested that the changes noted are diagnostic of the disease.

A New Periodical

The first number of *Folia Ophthalmologica Orientalia*,[2] under the editorship of Dr. Aryeh Feigenbaum of Jerusalem, has been issued. He and his colleagues may be warmly congratulated upon this new venture. The form, paper, printing, illustrations, and the manner of the presentation of the papers, are alike excellent. Particularly to be commended is the rule of attaching to each paper (and to the description of each figure) polyglot summaries. In addition to a summary in the language of the paper, there are adequate summaries in French, German, and other languages. The opening paper is a survey of fifty years of ophthalmic progress in Egypt, by Max Meyerhof. In this, he has a subject on which he can write with first-hand knowledge, and he has done so with feeling. Of particular interest is one of his remarks on the effects of the spread of scientific medicine. He says that the happy effects of the new era in Egypt have been, on the one hand, a sensible decrease of the deleterious eye disease and of blindness, and, on the other, a remarkable repression of quack practices, which thirty years ago were one of the plagues of Egypt. There is an interesting article by Dr. A. Trantas of Athens on the exploration of the ciliary and retrociliary region for foreign bodies. These regions are inaccessible by ordinary ophthalmoscopy, but can be explored in a satisfactory way by digital or diaphanoscopic pressure, so that normally hidden foreign bodies can be seen by direct ophthalmoscopy.

Drs. M. Sobhy Bey and E. I. Attie of Cairo give their experience of the total extraction of cataract by the erisiphake (Barraquer's method), and of the surgical treatment of immature cataract. They consider that there are material advantages in favour of intracapsular extraction, and maintain that the risks in this operation of loss of vitreous are balanced by the risks of incarceration of a shred of capsule between the wound edges when the cataract is removed from within the capsule. Dr. N. Shimkin of Caiffa, Palestine, records a case of bitemporal hemianopsia in pregnancy, and concludes that the symptom was due to compression of the chiasma by the pituitary body hypertrophied during pregnancy. There is also a report of the meeting of the Ophthalmic Section of the Palestine Jewish Medical Association.

Ireland

Mental Hospital Returns

The Department of Local Government and Public Health has issued to the committees of management of the district mental hospitals comparative returns of receipts and expenditure and average costs for the year ended March 31st, 1932. The gross expenditure was £813,120, or £13,631 less than in the preceding year; excluding repayment of loans of £60,636, the expenditure amounted to £752,484, as compared with £774,281 in 1930-1, a decrease of £21,797, although the average number of patients maintained increased from 17,409 to 17,549. The receipts amounted to £863,574, of which £765,085, or 89 per cent., came from the county and county borough councils, who received from the Government by way of capitation grant £150,768. This reduced the sum to be raised locally to £614,317, which, in so far as it was leviable by county councils off agricultural land, would be met partly by the agricultural grant. The principal receipts, other than money transferred by the councils to the credit of the committees of management, were: £39,998 from paying patients—which was slightly less than in the preceding year; £21,400 from the British Ministry of Pensions on behalf of British ex-Service patients; £7,000 from the Government on behalf of criminal lunatics; £12,107 from the sales of farm and garden produce, and £8,563 from officers as contributions towards superannuation. The major portion of the produce of mental hospital farms is not sold, but is consumed in the institutions, and so helps to reduce the cost of provisions. The average cost of maintenance, per patient, calculated on the gross expenditure less repayment of loans and miscellaneous receipts, was £41 8s. 11d. (or 15s. 10d. per week) in the district mental hospitals. In the Auxiliary Mental Hospital at Youghal the cost was £29 19s. 11d. (or 11s. 6d. per week). These costs are both less than the preceding year, when they were 16s. 5d. and 12s. 7d. per week respectively. The cost per patient was highest in Grangegorman and Portrane (£47 10s. 11d.), and lowest in Castlebar (£31 11s. 1d.). In the following institutions the cost was above the average: Mullingar, £47 2s. 8d.; Portlaoghise, £44 2s. 5d.; Carlow, £44 0s. 5d.; Kilkenny, £43 2s. 8d.; Limerick, £42 18s. 2d.; Waterford, £42 13s. 4d. In the following it was below the average: Killarney, £32 17s. 1d.; Cork, £37 8s. 10d.; Letterkenny, £37 12s. 11d.; Clonmel, £37 14s. 5d.; Monaghan, £38 0s. 1d.; Sligo, £39 18s. 6d.; Ennis, £40 2s.; Enniscorthy, £40 3s. 8d.; Ballinasloe, £40 19s. 4d.

Cost of Belfast Public Health

It is estimated that a reduction of £2,523 will be made in the cost of public health services in Belfast. Salaries and wages are responsible for the decrease in the anticipated spendings which is shown in practically every section of the estimates. Of the total of £55,436, salaries and wages account for no less than £29,271; this is £3,599 less than the amount required for the present year, and is equivalent to a saving of over 10 per cent. For the Public Health Department provision is made for a net sum of £15,760, a decrease of £1,148. Salaries and wages account for £12,667, fees for analyses £600, medical fees for notification £700, and printing, stationery, and advertising £650. The cost of the municipal laboratory is estimated at £854, against £936 in the present year; salaries and wages of £1,054 is the principal item, but this is set off by the expected receipt of £560 in fees for tests and vaccines. For the disinfecting station £1,411 is provided, against £1,297, the increase being due to the absence of any receipts for the disinfection of emigrants. Assuming the cost this year of the disinfection of emigrants to be £150, the estimate shows a slight decrease. Purdysburn Fever Hospital is estimated to cost £29,280, a decrease of £1,940; of this estimate £9,715 is provided for salaries and wages, a decrease on the present year of £1,135. Food for patients and staff is estimated at £4,500; medicines, disinfectants, surgical instruments, etc., at

£1,500 ; coal and coke at £2,600 ; repairs and improvements at £1,385 ; and loan charges at £8,390. Maintenance of patients is expected to produce receipts amounting to £1,500. Over £3,000 will be required for the superannuation of various former officers of the Department, and other items include the port sanitary work, £640 ; meat inspection, £2,926 ; treatment of venereal diseases, £1,590 ; and miscellaneous expenses of £715.

Scotland

Royal Infirmary of Edinburgh

At the annual meeting of the Court of Contributors to the Royal Infirmary of Edinburgh Lord Provost W. J. Thomson, who presided, said that the number of patients admitted during the year up to September 30th last had been 19,145, and the number of out-patients 66,200. The great change in recent years in the attitude of the public towards hospital treatment was indicated in the comparative figures for the year immediately before the war, which were 11,988 and 37,800 respectively. The popularity of the institution tended to become an embarrassment, despite the fact that many local hospitals had greatly increased their accommodation. Much progress had been made in radium treatment ; the Infirmary now had the use of over 1 gram of the element, and had opened Beechmount House as an auxiliary hospital with thirty-four beds for the treatment of cancer cases. This would add materially to the cost of running the Infirmary, and when the extension was completed it would be necessary to find an increase of annual revenue amounting to between £30,000 and £40,000. At the present time it cost over £175,000 a year to run the Infirmary, and only £120,000 was available from contributions, interest on invested funds, etc. A draft was submitted of a new constitution for the Court of Contributors, which aims at securing better representation on the Board of Management for various subscribing bodies. The report for the year showed that it had been necessary to draw on invested funds to the extent of £18,726, although this had been met by special donations and legacies. The total number of in-patients treated had been 20,049 as compared with 20,123 in 1931, and the average daily number in the institution had been 980. Of the patients admitted, 9,059 came from the city of Edinburgh and 10,086 from country districts. The waiting list had shown no reduction, the average number on the list having been 3,057. General subscriptions and donations in 1930–1 had fallen from £61,598 to £59,244, patients' donations from £4,436 to £3,798, and subscriptions of approved societies from £4,326 to £2,399. On the other hand, receipts under the Road Traffic Act had risen from £223 to £1,050. There had also been a serious diminution in legacies and special donations; in 1931 these had totalled £75,268, and in 1932 £69,947. The cost per occupied bed for the year, based on total expenditure and inclusive of out-patient departments, had been £160 5s. 5d., the average cost per patient treated having been £8 3s. 11d., and the average cost per day per patient 8s. 9d. In October the Board had obtained possession of the adjoining site of George Watson's College, on which it was proposed to erect a combined gynaecological and maternity hospital and a new home for nurses ; building operations would be commenced during 1932. The special committee set up two years ago to raise funds for this extension had obtained over £260,000. The necessary Bill to enable the directors of the Maternity Hospital to transfer the property of this trust to the Royal Infirmary had now passed through Parliament and received the Royal Assent. Progress had also been made with a new building to provide accommodation for patients suffering from skin and venereal diseases ; the two departments, although in one building, would be independent of one another.

Stirling District Mental Hospital

The annual report of Dr. R. B. Campbell, medical superintendent, Stirling District Mental Hospital, shows that there were 1,037 certified patients on the register at the close of the year to May 15th, 1932, of whom 583 were males and 454 females. During the year 259 certified patients had been admitted, 155 discharged, and 82 had died. The total number of certified cases under treatment had been 1,274, as compared with 1,282 in the previous year, and there had been thirty-six fewer admissions. Of the patients admitted, only forty-eight were found to be in average bodily health. Acute mental ailments had been the cause of admission of 108 patients, for whom reasonable hopes of recovery existed ; but 151 had been suffering from confirmed and chronic forms of insanity with little prospect of ultimate recovery. Senile insanity had been present in twenty-five patients, and twenty-six were cases of general paralysis or of gross brain disease. Encephalitis lethargica with progressive mental enfeeblement had been responsible for four admissions. With regard to causes, the mental breakdown had been the result of serious bodily illness in nineteen patients ; alcoholic excess in fifteen ; senility with failure of mental and physical powers in twenty-five ; syphilis in thirty-one ; and epilepsy in fifteen. Previous mental breakdown was noted in seventy-one patients, and in thirty-nine of these it had occurred at one or other of the critical periods of life, six being associated with childbirth. Twenty voluntary patients had been admitted during the year, of whom thirteen were rate-supported ; eighteen of these (five males and thirteen females) had left hospital cured, eleven returning home after less than three months' residence. There had been on the register at the beginning of the year forty-four patients maintained by the Ministry of Pensions, and during the year one more had been admitted ; one had died and one had been transferred to another mental hospital. Of the 155 patients discharged during the year, ninety-eight were recovered, giving a recovery rate, calculated on the number of admissions, of 37.1 for both sexes. Of these, sixty-two had been discharged within six months of admission and twenty-two after twelve months' residence. One patient had been discharged recovered after being resident in the hospital for seven years. Unrecovered cases discharged had numbered fifty-seven, the majority having been transferred to other institutions. Deaths during the year had numbered eighty-two, giving a death rate for the year of 8, calculated on the average number resident ; this was the lowest for many years. It is pointed out in the report that the recovery rate of 37 per cent. keeps at a satisfactory level, but it is regarded as unfortunate that this and similar institutions, primarily intended for the treatment of mental ailments, should have their hospital departments crowded with senile cases which could be satisfactorily cared for in some more suitable way without being certified as insane. It is suggested that such cases might be readily accommodated in the poorhouses throughout the country. Satisfactory results in cases of general paralysis have been obtained with tryparsamide, seven patients having been discharged to their homes after treatment. Great benefit has resulted from the use of electrotherapy employed in 231 cases. The occupational therapy department has continued to fulfil an important role ; it has been found of the greatest value for the less hopeful and chronic patients who have refused to be employed in ordinary ways, but whose interest has, sooner or later, been attracted by one or other of the various handicrafts.

England and Wales

The London County Council Hospitals

The general and special hospitals of the London County Council, which represent the most extensive municipal hospital organization in the world, are the subject of review in vol. iv (Part I) of the Annual Report of the Council, which covers the year 1931 (2s. 6d.). At the end of that year there were under the management of the Public Health Department of the Council forty-four general hospitals and institutions, with 27,553 beds, and thirty-one special hospitals, with 13,390 beds, while the staff of the hospital and ambulance services numbered 18,870 persons. Sir Frederick Menzies, the county medical officer of health, describes the formidable task with which the Council was entrusted when the hospitals and institutions of the Metropolitan Asylums Board and the boards of guardians were transferred under the Local Government Act, 1929. A number of the special hospitals transferred from the Board were of recent construction, and were planned for specific purposes, for which they are still being used. As they had been controlled by one central authority, with expert advisers, most of them were furnished with modern and efficient plant, and with equipment in keeping with the advance of medical science. No such uniformity and adequacy marked the general hospitals, which had been controlled by the boards of guardians. While these included at the one extreme institutions fairly comparable to the great voluntary hospitals, at the other extreme they fell far below that standard. Great inequalities were found as between one hospital and another, or even between different departments of the same hospital. In most of the guardians' institutions the general hospitals did not contain a sufficient number of beds to satisfy the needs of the population dependent upon them, and during the seasonal increase in illness in the winter serious shortage of beds was revealed. The Council set about the task of surveying all these hospitals and institutions and of removing the deficiencies. The purposes in view, as described by Sir Frederick Menzies, were to establish a satisfactory standard of accommodation, to furnish every hospital with modern and efficient plant, to organize suitable accommodation for special types of patients, to convert into suitable accommodation for cases of chronic illness such portions of the institutions as were capable of being so adapted, and to provide additional accommodation for acute cases. "It was clear," he states, "that the desired end could be attained only by pursuing steadfastly a policy of progress and reform over a long period of years. The position was dominated by the fact that the whole of the work which the problem demanded had to be carried out in hospitals which continued actively to exercise their functions. . . . It follows that any considerable improvement to a hospital must be accomplished section by section in successive stages, and must occupy a considerable period in its completion." He goes on to describe in detail the major and minor works undertaken and contemplated. References to these have appeared in these columns from time to time in reporting on the work and decisions of the London County Council.

With regard to pathological services, Sir Frederick Menzies says that experience gained since the application of the group laboratory system to the transferred hospitals and institutions has confirmed the conclusion that the absence of any organized laboratory system in the Poor Law hospitals was not only unsatisfactory from the point of view of the patient and the medical officer in charge of the case, but was also uneconomical. "The Council recognizes that modern medical treatment demands for its success a great deal more in the way of pathological investigation than has been provided in the past, and, moreover, that facilities for personal co-operation between the clinicians and the pathologists are now essential in the hospitals and institutions transferred to its care. In the past it had often been taught that the pathologist should have no knowledge of the clinical condition of the case under investigation, and that only in this way could an unbiased opinion on any specimen be obtained. This is now known to be fallacious, for in many cases it is only when the pathologist is in possession of full clinical details that he is able to give a just interpretation of the laboratory findings." Without the closest co-operation between pathologist and medical officer clinical work can never be entirely satisfactory. The report, which is a document of more than 200 pages, includes many statistical tables relating to the work of different groups of hospitals and services.

Harveian Society of London

At the hundred and first annual general meeting of the Harveian Society of London, held on January 12th at 11, Chandos Street, W., the retiring president, Mr. Cecil P. G. Wakeley, delivered his presidential address on the role of specialization. Mr. Wakeley recognized that specialization in medical practice was inevitable owing to the individual's inability to make himself familiar with the many and varied additions to his science and art, but in this country it was characterized by certain developments which were not beneficial to the community. For example, regional specialization in the art of surgery was largely artificial; it gave rise to various "ologies" which were of economic value to their practitioners but of dubious value to the patient. Again, the teaching of medicine and surgery in multiple special departments tended to divorce the student from the general principles. Mr. Wakeley contended that specialization in hospital practice should be determined by the genius of the individual practitioner and the interests of the patient; it should not be enforced on successful candidates for hospital appointments because it was convenient to hospital administration. For the treatment of the sick he agreed with Vesalius, who described the "distribution among different practitioners of the practical applications of the art" as mischievous. After expressing the gratification of the society that the distinguished work of two of their members, Sir Thomas Horder and Professor Frederick Hobday, had been recognized by His Majesty, Mr. Wakeley inducted the new president, Lieutenant-Colonel E. L. Gowlland, D.S.O., M.B., T.D., into the chair. Dr. Tom Hare and Dr. Macdonald Critchley (honorary secretaries) and Mr. Cecil P. G. Wakeley (honorary treasurer) were appointed.

Medical Society of Individual Psychology

Members of the Medical Society of Individual Psychology and their guests met for dinner on January 12th at the Florence Restaurant, Professor W. Langdon Brown being in the chair. After an excellent dinner Dr. F. G. Crookshank put forward the names of new members and associates; the acceptance of these brought the numbers of the society up to 97. The election of three honorary foreign members (Drs. Ziladi, Seif, and Adler) completed the century. Professor Langdon Brown, proposing the health of the society, said that it had been in existence only three years, during which time its membership has been increased tenfold. One of the advantages of individual psychology was that by its methods a large amount of psychology could be carried out by the general practitioner. One of the most important and successful ventures of the society had been the publication of the medical pamphlets under the editorship of Dr. Crookshank

and Dr. H. Weber. Dr. O. H. Woodcock, in proposing the health of the guests, eulogized them in turn. After an appreciative reference to Dr. Henry Devine's work he said that the only way to become intimate with Dr. Devine was to become one of his patients. In welcoming Dr. Graham Howe he remarked that the platform of the society was broad, and that no restriction to any theory of psychology was enforced. Referring to the presence of the representative of the *British Medical Journal*, he said that the *Journal*, in publishing accounts of meetings of the society, helped the general practitioner to become acquainted with the articles of its faith. The society, he continued, was greatly indebted to Mr. C. W. Daniel for publishing its medical pamphlets at some pecuniary loss to himself. Responding for the guests Dr. Devine said that, having lived for so long with psychotic patients, he was shy at being among so many normal people: nevertheless he felt in a complete state of psycho-somatic unity. Dr. Devine reminded his audience that Dr. Crookshank had worked for some time in a mental hospital, and he wished that he had continued in psychiatry. There was no more important movement in medicine than this society, the two heads of which were general physicians. The mass of neuroses would have to be treated by the general practitioner, and he thought that medical students should be taught the principles of psychology. Mr. C. W. Daniel gave a short account of the financial side of the production of the pamphlets, and told a good story about a plumber. Dr. Crookshank proposed the health of Professor and Mrs. Langdon Brown. He said that they were meeting under the shadow of Professor Langdon Brown's impending resignation from the chairmanship of the society. Since his occupation of the chair the society had gone steadily forward. Professor Langdon Brown replied in a brief and apt speech.

Central Midwives Board

At a meeting of the Central Midwives Board held on January 5th it was announced that a letter had been received from the Ministry of Health approving the existing rules for a further six months from December 31st, 1932. It was agreed to inform the Association of Inspectors of Midwives, in reply to their inquiry, that a midwife complies with the requirements of the Board if she records such material particulars as are furnished to her by the doctor or clinic, and that should the patient not have undergone a medical examination she should make a note to that effect. It was resolved to inform the various local supervising authorities, lecturers, and teachers that the Board understands that the *British Pharmacopoeia, 1932*, contains a standard for lysol *B.P.* which, in the Board's opinion, may be safely used as a disinfectant by midwives.

CORRESPONDENCE

The Hastings Window in Worcester Cathedral

SIR,—You permitted me to make an appeal to members of the Association for additional contributions to meet the balance due on the cost of the Memorial Window at Worcester Cathedral erected to the pious memory of our founder. When I wrote you on October 29th, 1932, there was a deficiency of £110; that has now been reduced to about £86. Members who have not seen the window will now have gained some idea of its beauty. The Medical Insurance Agency had the pleasing thought of sending a reproduction of the artist's design to all members as a Christmas greeting. I hope they will be so attracted by that picture—which, good though it is, can give but a small idea of the beauty of the window—that I shall, in response to this appeal, be so inundated with donations that I shall receive more than I need! In that happy event the balance will be transferred to the Sir Charles Hastings Charity Fund.—I am, etc.,

N. BISHOP HARMAN,
Treasurer, British Medical Association.

B.M.A. House, Tavistock Square, W.C.1,
January 12th.

The Biochemical Syndrome of Uraemia

SIR,—Dr. Paramore, in his letter published in your issue of January 7th concerning my paper on uraemia, raises some important questions. If I understand him aright, he suggests that dietetic restrictions at the onset of acute nephritis may succeed in abolishing the hypertension, fits, and oedema, and may even result in a more rapid restoration of renal function, with recovery of the patient. With regard to the latter I can only say that I wish it were so; but in spite of much work that has been done I know of no convincing evidence that dietetic restrictions at any stage of any type of nephritis can influence the progress of the renal changes. In fact, our almost complete inability to affect the course of the renal changes in nephritis is one of the most disheartening points about this disease. Clinical observations on such a point are necessarily untrustworthy. That dietetic factors may influence the hypertension and fits of acute nephritis is possible, but difficult to prove. That they influence the oedema, however, is undoubted, and this is a matter to which I should like to refer briefly.

As every medical student knows, nephritis is a very confusing subject. It is confusing because, in any given case, a number of different processes are at work which appear to have very little causal connexion with one another. These processes are: (1) Renal insufficiency, which if sufficiently severe (renal failure) will lead to frank uraemia. This renal insufficiency may be quite temporary, as in many cases of acute nephritis, or permanent and progressive, as in chronic nephritis. (2) Hypertension, cause unknown. (3) Fits, cause also unknown, but probably related to the hypertension and vasomotor spasm. (4) Oedema. (5) Albuminuria. When all these occur in one case no wonder there is confusion, especially as the relative preponderance of each factor may vary greatly from time to time and from case to case. It is instructive to note, however, that each one of these factors is common in conditions other than nephritis. To appreciate and assess a case of nephritis, therefore, one must be able to appreciate and assess each individual factor, and this can only be done when one has sufficient insight to distinguish the factors.

First, with regard to uraemia: this is a complicated condition resulting from renal failure, though in acute nephritis the failure seems to result more from a diminution of glomerular blood flow than from a failure of renal concentrating power (thus, a little urine may be manufactured which is highly concentrated, but, nevertheless, uraemia may result because the amount of urine manufactured is so small). Uraemia produces many symptoms; but fits, hypertension, and oedema are not among them. It may be inexorably progressive, or it may be transitory, as in acute nephritis, and disappear with the onset of diuresis. No one has any difficulty in saying that a patient dying from chronic nephritis is suffering from uraemia, but the clear recognition of minor and transient manifestations of the condition in other diseases is not so universal, especially when oedema, hypertension, fits, and albuminuria are prominent features

of the case. That uraemia is, however, a "self-contained" process, having no obligate connexion with these other factors, now seems established, and on rare occasions it may even be encountered (as in the case I described) in pure and uncomplicated form. This is a view which is founded upon much laborious work in many countries, and the observations in my paper are merely advanced as additional evidence in its support.

Oedema, then, is never the result of renal insufficiency, though it is very commonly associated with it. The problems surrounding the study of so-called "renal oedema" are many and intricate, but in general it appears that two main factors are involved. These are: (*a*) loss of certain of the protein constituents of the blood plasma into the urine (albuminuria) at a more rapid rate than can be compensated for by the tissues concerned, with resulting upset in the relative concentrations of the various plasma proteins (themselves very complicated substances of which our knowledge is scant); and (*b*) an obscure alteration in the functional efficiency of capillary endothelium in certain regions of the body which results in an escape of plasma protein into the tissue fluid in a manner closely analagous to that occurring in the glomeruli of the kidney in conditions of albuminuria. Since both of these factors tend to reduce the effective osmotic pressure of the blood plasma passing through the capillary bed, it becomes obvious how important they are in the mechanism of oedema formation. They are the basic abnormalities which enable the physician in charge to produce almost any degree of oedema he pleases by fortifying his patient with milk. For the elucidation of this difficult problem, which has thrown a flood of light upon many of the obscurities of nephritis, we are indebted to Dr. A. A. Epstein of New York.

Looked at from this angle, then, dietetic restriction is certainly important in the control of oedema, but only in so far as it includes salt and water (especially salt). The factors which produce the oedema are those mentioned above; administration of salt and water simply *allows the oedema to form*. Dr. Paramore's other remarks appear equally to the point, but call for no comment from me.—I am, etc.,

Dublin, Jan. 8th. GEOFFREY THOMPSON.

Death under Spinal Anaesthesia

SIR,—As it has been my privilege on many occasions to administer subarachnoid blocks for Mr. Norman Lake in gastric surgery, and always without anxiety, he will perhaps not be offended if I point out what I consider to be the weak spot in the case which he reports in your issue of January 14th (p. 77). This has no relation to vasomotor disturbances, but to the act of vomiting.

Successful vomiting depends upon the vigorous action of the respiratory and abdominal muscles, a closed glottis, and increased intra-abdominal and intrathoracic pressure acting upon the stomach and oesophagus. Propulsion and ejection of fluid from the pharynx is the essential requirement for safety. (Anyone who has been thus treated by a child on the opposite seat of a railway carriage will appreciate this mechanism.) With paralysed intercostals the patient is robbed of the muscles which are essential for good performance of the act, and under high thoracic blocks ineffectual vomiting may be observed. In any patient, therefore, in whom copious vomiting is likely to be encountered this method is, I believe, definitely contraindicated, and I agree with those anaesthetists who maintain that a push-fit intubation of the trachea is the only means of providing safety in these cases, although in a bad case this may be an extremely unpleasant and difficult performance.

I have maintained before that high spinal anaesthesia is not a short cut to safety in bad cases, but is applicable only in those patients who can afford to surrender a portion of their vital mechanism. Furthermore, the history of the toxic analgesics—of collapse in the consulting room, the dental chair, and the out-patient department—provides ample evidence that these drugs are all violent poisons to the human central nervous system, quite apart from nerve blocks. Not until these truths become more generally recognized will this method achieve the place it deserves in surgery.—I am, etc.,

London, W., Jan. 14th. W. HOWARD JONES.

Radium Therapy

SIR,—After reading the report of the Radium Technical Committee, published in the *Times* of January 6th and in the *Journal* of January 7th, one must conclude that the Radium Commission can no longer continue to countenance the use of radium by the interstitial method without inconsistency. Take the following extracts from the report:

"... it is therefore an essential factor in treatment that every element of tissue throughout the region treated should receive exactly the same amount of radiation."

"... there is, indeed, a general agreement upon the importance of obtaining a uniform field of radiation throughout the region under treatment."

Now consider these extracts side by side with the following passage taken from the *Westminster Hospital Reports* (xxi, p. 21) in the article on applied physics of radium, referring to the effect of distance on intensity of radiation:

"So much is this the case that in practice radium necrosis occurs at the surface of each needle of a group, while the intensity is yet insufficient between them to produce the necessary reactions."

Nothing could be more in conflict than the two former passages with the latter, and anyone with a superficial acquaintance with the physics of radium knows that by the interstitial method anything approaching an even radiation is impossible, unless the tubes are placed so close together that there are more tubes than tissues in the region under treatment. Therefore, if the views of the Technical Committee are to be followed out in practice, the curtain will fall on the interstitial use of radium. But if external radiation with large masses of radium is looked upon as the only useful method of employing this element, it is very important to know how many patients could be treated by this method. If every case must have the use of 5 grams of radium for a week or more, the proportion of the cases of cancer that can be treated would be so small that I think the vast amount of money required for this purpose would be better spent on some other line of research, unless the object in view is to acquire knowledge in readiness for the day, which may be very near, when rays of a penetration equal to the hardest gamma rays can be obtained from an *x*-ray tube. But if this is the object, why not carry on experiments in the meanwhile with the hardest *x* rays available.

I think it is generally admitted that the improved results from the use of radium were obtained when it was allowed to act for days instead of hours, or, in other words, when long-continued radiation of low intensity was substituted for short periods of radiation of high intensity. By increasing the distance of the *x*-ray tube from the patient, and also, if convenient, by diminishing the current, the time occupied by the delivery of a standard dose can be increased to any extent that is likely to be desirable. At a distance of about eight feet the time could be prolonged to about a week without difficulty. The difference between the application of *x* rays by such a method and external radium would be only one of wave-length, the importance of which is admitted in the report to be speculative, and yet I do not believe that experimental work on these lines has ever been done in this country.

No trouble was too great for him in helping a surgeon over difficulties. A writer in a lay journal has written of his "simplicity," but it is obvious that with such simplicity of aim he must have combined much astuteness, for none but a diplomat could have overcome without *éclat* the resistance which met his proposals for the establishment of military orthopaedic hospitals. As an operator he was neat and wasted no time, and his manipulative skill was of the highest order, as was his power of diagnosis by palpation. He was fully cognizant of the methods of bone-setters, but there was little or nothing that they could teach him, however highly placed might be their supporters.

On his seventieth birthday some of his friends and admirers entertained him at dinner, and presented him with the "Robert Jones Birthday Book," a volume of surgical essays. In the preface to it Lord Moynihan writes:

"Few men have ever possessed in so radiant a degree the genius for friendship. No one can be long in his company, none can work with him or play with him, without realizing not only the sweet simplicity of his character, but the greatness of his heart. . . . In a long and very intimate friendship I have never heard an unjust criticism, a cruel gibe, or a word of bitter cynicism on his lips. His personality radiates cheerfulness, good temper, and good will."

Sir Robert married Susie, daughter of Mr. William Evans, in 1887, and had two children. His son, who is a member of the Bar, succeeds to the title.

Sir JOHN LYNN-THOMAS writes:

There cannot be another Robert Jones, so I am proud of the privilege of sending my appreciation of a great man, whom I knew more intimately than any, excepting your late Editor, Dawson Williams. I am reminded of a happy incident by a photograph before me in which Robert Jones stands by one pillar and Dawson Williams by the other, in the Gardens, Castle Hotel, Brecon, with Lucas-Championnière standing on the steps between them and the provost of our new Medical School sitting at his feet. It was the occasion of celebrating a lawsuit lost through introducing a new method to this country into the orthopaedic treatment of fracture-dislocations near a joint. This method is to-day in general use, due in great part to the activities of the men in this little group, which led to an international protest against the verdict. It was the great war that brought great joy to the life of Robert Jones when he saw blazoned in the sky imperishable signs of victory, fruits of world-wide triumphs for the principles and practice originated by Hugh Owen Thomas at 11, Nelson Street, Liverpool, where he and I first met after my return from the South African war. It proved to be a strange experience, unforgettable from many standpoints, as I had to stay with the little patient I took to see him, giving me opportunities to observe and attend his popular Sunday service to the maimed poor. It was more than worth while—a revelation in the late H. O. Thomas's atmosphere in which his successor, the new wonder-maker, was at work. No anaesthetic but a hypnotizing manner when he refractured badly deformed old Colles's with a Thomas wrench, and completed treatment of children's club-feet by fracturing tibia and fibula with only his immensely strong hands. Splints and dressings were always in readiness, and the whole series would be treated and dressed within incredible time—two minutes for each would more than suffice.

In his wife he had a wonderful partner. When I was staying at their home later on, Mrs. Robert Jones would say in the morning, "We are going to have a quiet lunch to-day at half-past one." Fancy my surprise to find at table, sometimes, over a dozen medical men, Britishers and foreigners! After many repetitions I got used to it.

As chief of the Military Orthopaedic Department he proved to be a great organizer, tactful and firm, succeeding in establishing new types of curative institutions in the face of powerful recalcitrants. I had the flattering experience of being asked by a firm of well-known publishers to write a book on military orthopaedics, and on an impulse agreed. I recall the incident to illustrate the greatness of the character of Robert Jones. On asking him to write a chapter for the book he immediately consented. Later I realized that he was *the man*, and, as the result, his *Orthopaedic Surgery of Injuries* appeared in 1921. There cannot be another Robert Jones.

Sir W. I. DE C. WHEELER writes:

The death of Sir Robert Jones not only will be deeply regretted by the members of the medical profession throughout the world, but it will leave a feeling of vacancy in countless places. His recent ill-health gave rise to whispers of anxiety amongst his friends, but the tragedy of an impending fatal ending was put aside as impossible to contemplate.

I have shared with others the priceless privilege of close friendship for nearly twenty years. A letter was sent to him a week ago as a reminder of the affectionate welcome he would receive in Dublin if he could be present at the Annual Meeting of the British Medical Association next July. In paying tribute to Sir Robert Jones many will recount those great orthopaedic achievements which have received universal recognition and which have been acclaimed time and again by the surgeons of the world. Many will recall how, when they sought his advice, he was able in a moment to find a simple and effective solution to orthopaedic problems which had been regarded as insoluble by his pupils and contemporaries. My desire is to record with pride that I had the friendship of a man incapable of injustice, pre-eminently modest, and one who ranked co-operation far above checkmate, and who by word and deed was a high example to his many disciples. While insisting on thoroughness and efficiency in treatment, Sir Robert Jones overflowed with generosity and sympathetic consideration for those who consulted him. The crippled children will be amongst the many to miss the sunshine of his presence, but the path which led him to scientific achievement and a rare degree of personal charm will be still brightly illuminated by the light of his memory.

Dr. CHARLES MACALISTER writes:

The passing of Sir Robert Jones, who was my friend and colleague for more than half a century, has led to an opening of the book of memory concerning him. Its tablets tell the story of a remarkable life, serenely happy in itself, and radiating that happiness among all with whom he was brought in contact. Although I knew him as a vivacious, curly-headed boy, it was not until we were recently qualified that the intimate friendship began which prompts me to add some personal reminiscences to those which others have recorded concerning his career. When a student his versatile capabilities were demonstrated at a very early period. He had a knowledge of literature far beyond that of his academic work, and this led to a capacity for debate which became cultivated in a small society, consisting of four students, which met at weekly intervals in the house of his uncle, Mr. H. O. Thomas. Matters medical were, it is true, primarily discussed mainly as a means of revising the week's work, but when these were completed papers were read and debated on literary, political, and social questions, concerning which he in particular had very definite opinions. After qualification these four men invited other members of the profession and a number of laymen to join them, and thus in 1884 the progenitor of the Liverpool Medical and Literary Society, now approaching its jubilee, became formally constituted. One of the rules was: "The society shall exist for the purpose of enabling its members to

learn the art of speaking in public," and there is no doubt that this object was, and still is, fulfilled. The membership of the society has included most of the leading members of the profession in Liverpool, and many eminent in other work. Lord Justice Greer and Mr. Justice Rigby Swift were both on its roll. Sir Robert's library and his collection of pictures, which were both begun at the period of which I speak, bear testimony to his wide interests in literature and art. I must not conclude my mention of the above society without referring to what were termed the " after-meetings," limited to a few enthusiasts, who adjourned to a room in the basement and expended their pent-up physical energies by boxing, concerning which Robert Jones was both an adept and an authority. He had great physical strength, which could be noted when he bent metal splints with his hands or over his knee to adapt them to a limb.

Sir Robert began his career as a general surgeon, and at a very early age was on the staff of the Liverpool Stanley Hospital, which he left in 1889 on appointment to the Royal Southern Hospital. It was here that he developed his orthopaedic work, to which, from 1905 onwards, he devoted his whole attention. He enlisted the interest of many workers in the out-patient department, and also at his free Sunday morning clinics, to which poor patients flocked from far and wide. His reputation as an original thinker and teacher brought surgeons from all over the world to his clinics and operations, which were always attended by large numbers of them. In connexion with his out-patient work he adopted the co-operation of the Child Welfare Association, whose workers, after some training, kept an eye on the home conditions and feeding of the children. His interest in cripples and crippling led to a co-operation in the work of Dame Agnes Hunt, who instituted her extraordinary hospital at Baschurch about 1905. At first she brought the patients periodically to see Mr. Jones (as he then was) at the Royal Southern Hospital, to which they were conveyed from the station on trucks after a journey which must have involved a great deal of trouble to the railway servants. This was ended by a reversal of the procedure when Robert Jones made periodic visits to the hospital. In 1918, when the war had ended, he resigned his appointment at the Royal Southern Hospital, and devoted much of his attention to the establishment of a national endeavour to deal with the cripple problem, an endeavour which had Dame Agnes Hunt's hospital as its nucleus.

Another great and interesting work with which he was associated was the foundation of the Royal Liverpool Country Hospital for Children at Heswall. It originated between the years 1895 and 1898 in conversations with the writer concerning the difficulties of maintaining continuity of treatment for children suffering from chronic diseases, and materialized in the latter year, when wards were opened for a limited number of children as an independent institution in the convalescent home at West Kirby. A building committee under the chairmanship of Mr. Andrew Gibson was immediately appointed, and the hospital at Heswall was opened for patients in 1909. It is now, in association with the Liverpool Infirmary for Children, one of the largest children's hospitals in the kingdom. Sir Robert Jones was honorary surgeon to it from the time of its inception. One of the wards bears his name and another that of Lady Jones, in whose memory it was built.

In concluding these recollections one must refer to Sir Robert's gracious social attributes. At his home he gathered round him men and women representing all kinds of interests. There one met surgeons and physicians of all nationalities, distinguished politicians, authors, judges, lawyers, artists, actors, and literary men of every kind, in addition to his immediate friends and intimates. He had a profound love of humanity, and an especial love for the working classes and for their children, to whom he was everlastingly kind. I remember that year by year he sent every child that could be moved from his hospital to the pantomime, and in many other ways demonstrated the kindness and generosity which were essential features of his character. Sir Robert created a great work which will live in the history of surgery, and it, in association with his name, will ever remain the " monument of a vanished mind."

MR. HARRY PLATT writes:

My debt to Sir Robert was twofold, and I pay this tribute to him both as a patient and as a pupil. He would often remind me that he had known me longer than any of my contemporary colleagues, for it is now a little more than forty years since I paid my first visit to 11, Nelson Street, and joined the countless host of his devoted child patients. Little did I think during those days of invalidism that in the fullness of time I should once more come under the spell of his radiant presence. Every detail of our first encounter is clear in my memory: the long wait—for this was before the days of fixed appointments—and the dread of what might happen if a knee-joint, painful, swollen, and flexed, were roughly handled. As he entered the room all fears were dispelled, and I submitted my limb to his gentle touch with implicit trust. Long afterwards I was to witness on many occasions the magical effect of his presence on other children similarly afflicted.

With others of my generation, I can count myself fortunate to have been admitted to that chosen band of disciples to whom Sir Robert entrusted the care of the crippled soldier in the special military surgical hospitals. Out of this work came the British Orthopaedic Association, with Sir Robert as our perpetual president, and the object of our continuous devotion, loyalty, and affection. Through him we attained to a comradeship amongst ourselves such as exists in no other group of British surgeons. We tried hard, each one of us, to fashion ourselves in his image. Who can forget the charm of those early committee meetings, held during and after dinner at the Reform Club in London, with the official business constantly interrupted by animated discussions on irrelevant subjects, for " R. J." could never control any committee! The Birthday Volume presented to him on his seventieth birthday was the open expression of what we felt about him, and for which we could never find adequate words when in his presence. It was my special privilege to be chosen by Sir Robert as his collaborator in the revision of the great textbook on orthopaedic surgery which he had written with Lovett of Boston, shortly after the war. The second edition proved to be a mighty task, which lasted two and a half years. During this time I spent many week-ends at Liverpool; our programme was a quiet dinner on Saturday evening, early to bed, and a full day's work on the Sunday, broken only by a walk round Prince's Park after luncheon, accompanied by his beloved dogs. We read the first edition of his book line by line, and he submitted every statement to a most intense and critical scrutiny. From those long hours of intimate communion I learnt to marvel at the profundity of his academic knowledge and his intellectual vigour. This was an aspect of his many-sided genius not always revealed to the ordinary spectator of his amazing career as a great practical surgeon.

And so he has passed on, and left to us a great inheritance. May we prove worthy of it.

HARRY LEE, F.R.C.S.

The death of Mr. Harry Lee at the comparatively early age of 50, sudden and unexpected as it was, has caused profound and widespread sorrow in the West Riding. On Wednesday, January 11th, he was seemingly in his customary health and carrying on his usual work at his rooms. While driving himself home in the afternoon he apparently had some kind of seizure, which resulted in death within a very short time.

A native of Dewsbury, he was known to a good many people in Leeds as the nephew of the late Dr. Edwin Lee, a greatly respected and widely known practitioner, who at one time was president of the Leeds and West Riding Medico-Chirurgical Society. Mr. Harry Lee graduated as Bachelor of Arts at Cambridge, where also he took the degrees of M.B., B.Ch. in 1910. His clinical work as a student was mostly done at Guy's Hospital; he took his F.R.C.S. in 1911. When Mr. Michael Teale left Leeds in 1913, Lee was elected surgeon to the Leeds Public Dispensary, where he had a large clinic, remaining on the staff till 1922. When in 1919 Mr. H. Secker Walker resigned his post as honorary ophthalmic surgeon to the General Infirmary at Leeds, Lee was elected to the staff, and received a most cordial welcome from everyone. He was also appointed lecturer in ophthalmology in the University of Leeds. A steady worker, quiet in his methods and most efficient in every department of his work, he was respected and loved by every member of the staff, and by the students, to whom he acted as a kindly and sympathetic teacher. Those who are best competent to speak with authority of his professional work are agreed that in his hands the reputation of the Infirmary has been enhanced. During the war he served as a captain in the R.A.M.C.(T.), and for some time was ophthalmic specialist to the British Expeditionary Force and at Chelsea. In his younger days, when at St. John's College, Cambridge, he was an ardent Rugby football player, and got his "Blue" as full-back. Since settling in Leeds he had been a constant golfer with his friends and colleagues at Allwoodley. There was something singularly engaging in Lee's character, with its easy combination of kindness, sympathy, and courtesy, and no one who knew him will ever forget him. He leaves a widow and two sons, to whom the sympathy of everyone is extended.

Dr. PETER MACDONALD writes:

The North of England has suffered a grievous loss in the passing away of Mr. Harry Lee, who died suddenly at the wheel of his motor car last Wednesday. He was senior honorary ophthalmic surgeon at the Leeds General Infirmary and lecturer in ophthalmology at Leeds University.

Presumably others better qualified to speak than I will write of his work and attainments, but I would like to say something of him as a man and a friend. Gifted with an unusual charm of manner he endeared himself to all, and one of the pleasures of going to the meetings of the North of England Ophthalmological Society, of which he has been president, was to meet him; and this was particularly so at Leeds, where he made such a genial host. His opinions there, as elsewhere, were received with respect, and all the more so as he was a generous colleague, always willing to help when his advice was sought. He had that characteristic which marks the really big man, of always being receptive of ideas and of deferring to the opinions of others whose attainments were obviously not as great as his own. To me, personally, the loss of a friend and of a trusted colleague to whom I could always turn for help in my work is very great; but such was the magnetism of his personality that I do not so much mourn that he has died as rejoice that he lived. I am sure that the hearts of all his colleagues will go out to his wife and children.

The Board of Management of the General Infirmary have adopted the following resolution: "The Board of Management of the General Infirmary, having learned with profound regret of the sudden and untimely death on January 11th of Mr. Harry Lee, honorary ophthalmic surgeon, desire to place on record their deep sense of loss and their appreciation of his valuable services to the Infirmary during the thirteen years he has been actively associated with it as a member of the honorary medical staff. The Board also desire to express their deep sympathy with Mrs. Lee and her family in the great loss they have sustained."

The funeral service was held at St. Matthew's Church, Chapel Allerton, where a large congregation assembled to pay respect at the passing of a good friend and colleague. A memorial service was also held in the chapel of the Leeds General Infirmary, which was attended by some sixty members of the medical and nursing staffs who were unable to attend the service at Chapel Allerton.

DR. WILLIAM GALBRAITH

A remarkable record of public service was ended when Dr. William Galbraith of Gosforth, Newcastle, passed away on January 6th at the age of 87. A typical Scot, born at Ayr, he was educated at Ayr Academy, and qualified in medicine and surgery at Edinburgh University. For the unusual spell of fifty years he was in practice at Gosforth, and during that time held with great efficiency the appointments of medical officer of health, police surgeon, and public vaccinator. During this half-century he initiated many public health improvements, which were reflected in a decreasing death rate to such an extent that Gosforth was locally known as a "health resort." He successfully combated many epidemics—particularly of small-pox—and was a firm believer in efficient four-mark vaccination. Ten years ago, when the disease was prevalent in Northumberland, Gosforth remained free.

As a physician he was renowned amongst his fellow practitioners as a quiet and remarkably accurate diagnostician. He was a founder and the oldest member of the Gosforth Medical Association, and a member of the British Medical Association. He was the true type of the ideal family doctor, to whom the interests of his patients and profession came first and the business side last—frequently to his own personal loss. He was generous and open-handed to a degree, and his patients, for whom he had always a cheery word, loved and honoured him. His healthy physique and smiling ruddy face gave a cheering stimulus to everyone. What he has done for Gosforth and its inhabitants, both publicly and privately, can never be fully known.

Dr. Galbraith's long life was fully occupied by his work and his sport. As a young man he had been a good footballer and cricketer, and when aged "three score years and ten" he could easily beat much younger men at golf, while in the evenings he always enjoyed his game of bridge. His annual holiday was spent in shooting and fishing in his beloved Scotland. Dr. Galbraith's cheery smile and infectious laugh will remain long in the memory of his multitude of friends. He is survived by two daughters, who have faithfully cared for him during his long life, and to whom the deepest sympathy is extended.

The following well-known foreign medical men have recently died: Dr. MILAN JANU, founder of the Franco-Czechoslovak Medical Society, aged 47; and Dr. LEHNHOFF WYLD, who discovered sulfarsenol.

Universities and Colleges

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A quarterly Council meeting was held on January 12th, when the president, Sir Holburt Waring, was in the chair.

The secretary reported the death, on December 21st, 1932, of Mr. Herbert Sherwell Clogg, chairman of the Court of Examiners, and the death, on January 3rd, of Mr. Cecil Fowler Beadles, curator of the museum. A vote of condolence was passed in each case.

The Hallett prize was awarded to S. G. Nardell of King's College.

Mr. T. W. P. Lawrence was appointed acting pathological curator of the Museum for the rest of the current collegiate year.

Mr. R. E. Kelly was re-elected a member of the Court of the University of Liverpool for three years, from January 1st.

Sir *Cuthbert Wallace was appointed Hunterian Orator for* 1934.

The course of lectures for 1933 is arranged as follows: January 23rd, Professor Arthur Edmunds, Unsuccessful appendicectomy; January 25th, Professor Harold Burrows, The induction of cancer in animals by pure chemical substances; January 27th, Professor W. E. M. Wardill, The principles of treatment of cleft-palate; January 30th, Professor Kenneth Walker, Perurethral operations on the prostate; February 1st, Professor P. H. Mitchiner, An epitome of the treatment of burns and scalds, with special reference to the use of tannic acid; February 3rd, Professor J. Paterson Ross, Sympathectomy as an experiment in human physiology; February 6th, Professor H. P. Winsbury-White, The paths of infection between the genital organs and the urinary tract, with remarks on the ascent of infection from the bladder to the kidneys; February 8th, Professor Stanford Cade, Radiation treatment of cancer of the mouth and pharynx; February 10th, Professor H. Jackson Burrows, Tissue culture in its relationship to surgical pathology; February 13th, Mr. P. N. B. Odgers, Some points in the anatomy of the lumbar and lumbo-sacral diarthrodial joints in man; February 15th, Professor R. J. S. McDowall, Experimental shock, with special reference to anaesthesia; February 17th, Mr. R. W. Raven, Diverticula of the pharynx and oesophagus, with special reference to the morphological and embryological aspects; February 20th, Professor Laurence O'Shaughnessy, Thoracic surgery—the factor of post-operative infection; February 23rd, Professor G. A. Mason, The surgical significance of the vitelline duct; February 24th, Professor E. R. Flint, Some observations on pre-operative procedure. The lecture hour is 5 p.m.

The following diplomas were granted jointly with the Royal College of Physicians:

PUBLIC HEALTH.—S. N. Bandyopadhya, W. D. T. Brunyate, Alice E. N. Gilby, A. W. Johns, S. Knight, M. Singh, M. M. Syddiq, L. D. Williams, H. M. Willoughby.

TROPICAL MEDICINE AND HYGIENE.—Mabel G. Brodie, D. D. Karunaratna, C. K. Lakshmanan, V. Nadarajah.

PSYCHOLOGICAL MEDICINE.—Sophia Antonovitch, G. G. Brown, S. Carden, H. W. D. Crook, J. L. Faull, B. M. C. Gilsenan, K. Hazell, J. K. C. Liddell, J. R. Murray, F. E. Norris, Major T. P. Parr, R.A.M.C., N. Rawstron, G. M. Smith, G. V. Stephenson.

LARYNGOLOGY AND OTOLOGY.—R. Evans, L. Jacobson, J. Mazell, H. C. Meathrel, K. V. B. Pillai, A. F. Quayle, A. Rakoff, A. Rose, B. K. Sheorey, M. R. Sheridan, I. B. Thorburn.

Diplomas in Medical Radiology were granted jointly with the Royal College of Physicians to A. A. Digges la Touche and G. D. Steven.

Medical News

Sir Lenthal Cheatle was installed as an honorary Fellow of the American College of Surgeons at the last meeting of the College held in St. Louis.

Sir Henry Brackenbury, Chairman of Council of the British Medical Association, will deliver an address on "The essentials of a national medical service," at the meeting of the Brighton Division of the Association to be held at the Royal Pavilion, Brighton, on Friday, February 3rd, at 3 p.m. Members of local authorities, medical officers of health, boards of management of voluntary hospitals, insurance committees, and selected social workers in Sussex have been invited to attend, together with members of the Sussex Branch of the British Medical Association. At a further meeting of the Division, to be held at 8.30 on the same evening, at the Royal Pavilion, Sir Henry Brackenbury will speak on "The sterilization of the unfit in its relation to private medical practice—medical certification." The latter meeting is limited to members of the medical profession.

Professor E. Mellanby will give two lectures on iodine and the thyroid gland in the Governors' Hall, St. Thomas's Hospital, at 5 p.m., on January 26th and 27th.

Two lectures under the auspices of the Save the Children Fund Child-Protection Committee will be given at Caxton Hall, Westminster, on Fridays, January 27th and February 24th, at 5.30 p.m. The subject of the first, by Captain R. S. Rattray, is "The African child in proverb, in folk-lore, and in fact"; that of the second, by Dr. J. H. Driberg, is "Practical uses of anthropological study."

Wing Commander G. S. Marshall, M.R.C.S., L.R.C.P., will give a lecture on the physiological limitations of flying, before the Royal Aeronautical Society on Thursday, January 26th, at 6.30 p.m., in the lecture hall of the Royal Society of Arts (16, John Street, Adelphi, W.C.2). It is hoped that all those who have had any experience of the physiological limitations of the human body will attend the lecture, and, if possible, give those present the benefit of their experience. Tickets are not required, but the visitors' book must be signed on entering the hall.

At the meeting of the Medico-Legal Society, to be held at 11, Chandos Street, W.1, on Thursday, January 26th, at 8.30 p.m., Dr. Godfrey Carter will discuss an unusual case of fractured spine and a case of prussic acid poisoning.

A joint meeting of the Sections of Epidemiology and State Medicine and Medicine of the Royal Society of Medicine will be held at 1, Wimpole Street, W.1, on Tuesday, January 24th, at 5 p.m., when a discussion on undulant fever will be opened by Dr. W. E. Hume, Sir Weldon Dalrymple-Champneys, and Dr. I. Walker Hall.

Two meetings of the Tuberculosis Association will be held at the London School of Hygiene, Keppel Street, W.C.1, to-day (Friday). At 5.15 p.m. Dr. S. Lyle Cummins, David Davies Professor of Tuberculosis, University College, South Wales, will read a paper on tuberculosis and the South African native. At 8.15 p.m. a paper on pulmonary asbestosis, its clinical, pathological, and radiological aspects and tuberculosis risk, will be read by Dr. P. Ellman.

The next monthly clinical meeting for medical practitioners will be given at the Hospital for Epilepsy and Paralysis, Maida Vale, W.9, on Thursday, January 26th, at 3 p.m., when Dr. Wilfred Harris will demonstrate. Tea will be provided, and it will be a convenience if those intending to be present will send a card to the secretary.

The second lecture in the series "Practical problems in medicine and surgery," arranged by the Fellowship of Medicine and Post-Graduate Medical Association, will take place at the Medical Society of London, 11, Chandos Street, W.1, on Tuesday, January 24th, at 4 p.m., when Dr. Godfrey Bamber will lecture on some affections of the skin in childhood. On Thursday, January 26th, there will be a special evening demonstration of diseases of children, at the National Temperance Hospital, Hampstead Road, at 8 p.m. Cases will be shown by two physicians and one surgeon; post-graduates will have the opportunity of examining the cases, and will then be questioned and lectured on the diagnosis and treatment. A course in dermatology will be given at St. John's Hospital, from January 30th to February 25th, which will include clinical instruction daily, and lectures on Tuesdays and Thursdays. Forthcoming courses include a course in gynaecology at the Chelsea Hospital, from February 6th to 18th (mornings and/or afternoons); a course in diseases of the chest at the Brompton Hospital, from February 6th to 11th (all-day instruction); a course in ante-natal treatment at the Royal Free Hospital, from February 3rd to March 11th, on Fridays, at 5 p.m.; a week-end course in physical medicine at the London Clinic and Institute of Physical Medicine, on Saturday, February 11th, and Sunday, February 12th. Courses, lectures, and demonstrations are open only to Members and Associates of the Fellowship of Medicine.

A Congress of the North-West German Society for the Treatment of Internal Complaints will be held at the Allgemein Krankenhaus Barmbeck, Hamburg, on January 27th and 28th. The president desires to extend a cordial welcome to medical men of other countries who, being in Hamburg, may wish to attend this meeting, of which further particulars will be available at the British Consulate-General, Hamburg.

Among the latest contributions to King Edward's Hospital Fund for London are the sum of £1,000, being the annual subscription of His Majesty the King, Patron of the Fund, £105, the annual subscription of Her Majesty the Queen, and £200, being the annual subscription of H.R.H. the Prince of Wales.

The eulogy of *Léon Labbé*, a former president of the Académie de Médecine, as well as an eminent surgeon and politician, who was born in 1832 and died in 1916, was delivered before that body on December 13th, 1932, by Professor J. L. Faure.

Dr. Louis Martin, subdirector of the Institut Pasteur and director of the Hôpital Pasteur, has been nominated Grand Officer of the *Legion of Honour*.

A Union of German Biologists has recently been formed, with Professor Lehmann of Tübingen as president.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are MUSEUM 9861, 9862, 9863, and 9864 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:
EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscra Westcent, London.*

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Separation of Finger-nails

Dr. C. F. DRUITT (Alvaston, Derby) would be glad of suggestions as to the cause and treatment of a case of separation of all finger-nails from the matrix. He writes: A small portion at the proximal end may remain attached and looks healthy, while the separated portion is black in colour. Laboratory investigation fails to reveal the presence of any active disease. Cutting the nails away where they are detached seems of no avail, and makes the fingers tender at the tips. The patient is a middle-aged lady in good health.

Cracks on Nails

Dr. GEORGE BLACK (Tomintoul) writes: Keep nails short, and paint them once a week or so with acetone collodion.

Scabies

Dr. T. LUCAS HILLIER (Boscastle) writes: Having suffered whilst in China from the complaint for which "Acarus" seeks treatment, and having tried ung. sulph. *ad nauseam* with only slight relief, I purchased a bottle of "mitigal" on the recommendation of a ship's officer. One application of this preparation (which is free from irritating effects and unpleasant odour, clean in application, and does not spoil linen) and I was free from this agitating complaint. So effective was this substance that I still have most of the original bottle left. The preparation is made by Bayer Products, Ltd. (19, St. Dunstan's Hill, E.C.3).

Dr. MAURICE NEWMAN (Liverpool) writes: I assume that "Acarus's" patient has had an intensive treatment with sulphur—a hot bath every twelve hours, the skin rubbed with a brush, and the whole body thoroughly rubbed with sulphur ointment in large quantities. This procedure, repeated for five days, should ensure the death of the parasite, provided that there has been no reinfection from the patient's clothes, which should have been thoroughly disinfected. If irritation persists the patient is probably suffering from post-scabietic pruritus, which may be due either to the nervous condition or to excessive sulphur medication. For the latter, hot baths should be taken and calamine oil applied to the skin. If the irritation is troublesome at night "mitigal" or "dermatol" may be applied. Bromide and valerian will help the nervous condition, while a change of air is often very necessary.

Income Tax

Appointments—Expenses—Special Study

"J. B. H." holds an appointment at a hospital, and inquires as to the allowance of expenses incurred (*a*) in studying for the D.P.H., (*b*) in carrying out the duties of a separate (honorary) appointment, and (*c*) in maintaining his membership of certain learned societies.

*** (*a*) Not allowable; they are incurred to improve his knowledge and prospects, and are in the nature of capital outlay. (*b*) Not allowable, unless he is expected by the authorities of his own hospital to carry out these additional duties; "J. B. H." is assessed for his hospital emoluments only, and those expenses were not incurred in carrying out the *hospital* duties. (*c*) Allowable if the terms of his appointment (expressed or implied) require his membership of the societies in question—otherwise not allowable.

LETTERS, NOTES, ETC.

Treatment of Tinea Imbricata

Dr. J. A. S. GOONAWÀRDENA (London, N.W.1) writes: The usual methods of treatment adopted for this condition appear to be very unsatisfactory. While working in the interior of Ceylon ten years ago I came across three cases. One was a man of about 50, the other two were boys between 15 and 18 years of age. All three patients were put on different forms of treatment, and lotions, applications of tr. iodi, ointments of sulphur, mercury, salicylic acid, resorcin, and chrysarobin were tried without effect on the lesions. Intravenous medication was then tried with such drugs as arsenobenzol, antimony, etc. Finally, the elderly patient, who had been afflicted for five years, was given, bi-weekly, intravenous injections of a solution consisting of iodine 1 part, pot. iod. 2, aq. dest. 300, commencing with 2 c.cm. diluted up to 10 c.cm. with distilled water, the doses being gradually increased up to 7 or 10 c.cm. The lesions disappeared completely with about eight injections. Similar success was obtained with the boys in three to four weeks. It was found that a simple ointment such as ung. sulph. or ung. hydrarg., ineffective by itself, was helpful in clearing up the lesions. No drugs, excepting ordinary tonics, were administered orally. The boys were subsequently lost sight of, but the other case—the worst one—has been free from the disease for a period of nine years, and when last seen his skin looked perfectly normal.

A Contraceptive Museum

Dr. EVELYN FISHER (Barnes) writes: Readers of the report of Mr. Voge's address on contraception (*Journal*, January 7th, p. 16) may be interested to know of the existence of a contraceptive museum founded as far back as 1921. This is at the headquarters of the Constructive Birth Control Society, 108, Whitfield Street, Tottenham Court Road, and may be visited by doctors who are interested. It comprises a unique collection of appliances, and illustrates in a very practical manner the dangers to be avoided and the requirements to be sought after in the ideal contraceptive. In addition there is a most useful library, from which may be obtained books bearing on birth control in all its aspects—medical, social, religious, racial, etc.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 51, 52, 53, 56, 57, and 58 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement at page 19.*

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

36 The Electrocardiogram in Late Middle Life

J. JENSEN, M. SMITH, and E. D. CARTWRIGHT (*Amer. Heart Journ.*, August, 1932, p. 718) have studied the electrocardiogram in fifty persons between the ages of 50 and 65 who were free from symptoms or signs of cardiovascular disease. This investigation was undertaken in order to determine whether among individuals of this age group electrocardiographic changes occur which, although unusual in earlier life, may be regarded as physiological at the later age. Records were taken in both sitting and supine positions, and sometimes also in inspiration and expiration. The authors refer to Fahr's estimate that 23 per cent. of deaths after the age of 50 are due to heart disease, and deduce from this the probability that, among their fully investigated series of fifty, few, if any, cases of "hidden" heart disease could have been present. It was found that the following electrocardiographic modifications, hitherto sometimes considered pathological, were frequent and therefore of no serious significance: diphasic or iso-electric P waves in Lead I or inverted P waves in Lead III becoming upright on deep inspiration; slurring of QRS complexes, provided that the QRS interval was less that 0.1 second; transverse heart; isolated left axis deviation; and moderate inversion of T in Lead III. Certain other recognized changes were not found, and should therefore be looked on with suspicion: inverted P waves in Lead I or II, or in Lead III if they do not become upright on deep inspiration; inversion of T waves in Lead I or II if not becoming upright with deep inspiration; PR intervals exceeding 0.2 second; and QRS intervals exceeding 0.1 second, or ST intervals exceeding approximately 0.35 second. No characteristic "age changes" could be made out in the group studied.

37 Tuberculin Reaction in Rubella

H. KOCH (*Wien. med. Woch.*, November 5th, 1932, p. 1397) states that, in contrast with measles, in which a previously positive Pirquet reaction usually becomes negative during the eruptive period, this reaction is not affected in rubella as a rule. During a recent epidemic of rubella in Vienna, however, he saw a boy, aged 3½, admitted to hospital for hilus tuberculosis and a strongly positive Pirquet reaction, in whom the reaction became negative during the eruptive period of an unusually severe attack of rubella. Measles could be excluded by a previous history of that disease, the typical character of the eruption, and the glandular enlargement. Koch attributes the disappearance of the reaction to the unusual severity of the eruption, and alludes to cases of attenuated measles in which, as in most cases of rubella, a positive reaction does not become negative.

38 Primary and Toxic Forms of Hypertension

L. POPPER (*Arch. des Mal. du Cœur*, September, 1932, p. 513) classifies hypertension into (1) primary, and (2) toxic or infective types. The first group includes all conditions of hypertonus of the arteries and arterioles leading to eccentric hypertrophy of the left ventricle, and usually to hypertension with tortuous arteries, whether or not renal involvement ultimately ensues. The second group comprises those varieties of hypertension due to such toxaemias as those occurring in pregnancy and lead poisoning. Here the ventricular hypertrophy is concentric, and the arteries are straight and narrow. Among 1,031 patients with hypertension observed over a period of ten years, 754 belonged to the primary group, 56 to the toxic group, while in 221 a mixed form was present. Death ensued in 249 of those afflicted with primary hypertension; when it was not due to intercurrent maladies it followed cerebral complications, heart failure, or anaemia. About half of the toxic hypertensive patients died, 14 of them from renal insufficiency, the age at death being generally considerably earlier than in the primary group. Popper remarks that primary hypertension is largely familial, and manifests itself usually by headache, vertigo, occipital neuralgia, and easy fatigability. From the fact that cerebral attacks occur less commonly in toxic hypertension, he infers that hypertension is not the only factor concerned in the production of such cerebral lesions, and that variations in the structure of the vascular wall probably play an important part. Among 454 primary hypertensives with cerebral lesions, the left hemisphere was affected more commonly than the right, the lesion, whether right or left, being fatal in about one-third of all cases.

39 Incidence of Diabetes in Finland

Ö. HOLSTI (*Nord. Med. Tidskrift*, September 3rd, 1932, p. 646) publishes tables and graphs showing the incidence of diabetes in the Scandinavian capitals and New York in five-year periods from 1911 to 1930. Throughout this time the diabetes rate was lowest in Helsingfors and highest in New York. In 1929 the consumption of sugar in Finland was 27.4 kilos per head, whereas in the same year in the U.S.A. it was 50.3 kilos. In Finland in 1913 it was only 15.9. Though the author does not consider the increased consumption of sugar to be the sole cause of the rise in the diabetic rate in Finland in the period under review, he attaches considerable importance to it. In Helsingfors most of the deaths among diabetics were due to associate diseases, notably infectious diseases in young persons and degenerative diseases of the heart and blood vessels in older persons. In the five-year period 1926–30 only 15.18 per cent. of all the deaths among diabetics in Helsingfors were due to diabetic coma.

Surgery

40 Phlegmonous Gastritis

W. L. WATSON (*Amer. Journ. Surg.*, October, 1932, p. 113) describes phlegmonous gastritis as a severe inflammatory process of the stomach, progressing to purulent infiltration and even necrosis of the stomach wall. There are two definite forms of the disease: one in which there is a collection of pus or a localized abscess in the wall of the stomach; and another more diffuse form in which a widespread inflammatory process may involve the entire stomach and extend into the oesophagus proximally and the duodenum distally. This latter form of the disease is twice as common as the circumscribed form; its operative results are less satisfactory, since a diffuse peritonitis is usually present. The origin of the inflammatory process may be either local or metastatic. Cases of local origin include those in which a gastric carcinoma or ulcer is present, and those in which gastric surgery has been performed. In the metastatic group are found a larger number of cases, which are seen in conjunction with puerperal fever, septicaemia, tonsillitis, erysipelas, or furunculosis. Gastric phlegmon has also occurred in cases of small-pox, scarlet fever, and acute polyarthritis. Constitutional predisposing causes include exhaustion, alcoholism, chronic gastritis, and hypo-acidity of the gastric juice. The streptococcus is isolated in 70 per cent. of cases; symptoms of the disease are not characteristic; there is usually a history of previous gastric distress, followed by the sudden onset of severe upper abdominal pain, which is at first localized, and is increased by pressure in the epigastrium. Later, when peritonitis develops, the pain becomes generalized. Vomiting occurs throughout the course of the disease, and fever is a

common symptom. The patient appears acutely ill, and later becomes dehydrated, finally going into delirium and collapse. Diagnosis is rarely made before operation, and the prognosis, especially in the diffuse form of the disease, is grave. In the localized type the abscess may rupture into the stomach and recovery ensue, or the involved portion of the stomach may be resected. Of eighteen cases in which gastric resection was performed eight recovered. In the extensive diffuse type of gastric phlegmon a palliative jejunostomy and abdominal drainage are advisable. A case is reported in which this form of treatment was tried, but the patient died three days after the operation.

41 Treatment of Biliary Lithiasis

Without dilating on the relative merits of cholecystectomy or cholecystostomy in the treatment of biliary lithiasis, D. PRAT (*Rev. Sud-Amér. de Méd. et de Chir.*, September, 1932, p. 749) discusses the advisability of drainage following these procedures. After cholecystostomy or drainage of the hepatic canal the bile is found to be of a dark, almost inky, hue, which returns to the normal golden-yellow colour after a period varying from ten days to a month ; the dark colour is due to concentration of the biliary salts and pigments. The opinions of various authorities are cited as regards its pathogenesis. Desplas and Dalsace believe that black bile is of hepatic origin, while Chiray, Davel, and Amy consider it to be vesicular. Prat discusses these statements and the significance of vesicular, canalicular, and hepatic black bile, and points out that in cholecystectomy without drainage the bile may remain black or infected for a certain period. From a study of all these points he strongly advocates drainage after all operations for biliary lithiasis ; this should be continued until the bile returns to its normal colour. Since an ordinary drainage tube may become detached owing to absorption of its retaining sutures, the use of a special tube, Kehr's tube or Pezzer's sound, is advised. The presence of calculi is often overlooked ; two cases are mentioned in illustration of this. To avoid this complication a large drain should be employed and a most careful emptying of the vesicular canals be performed at the time of operation and after radiography with lipiodol.

42 Fractures of the Vertebral Column

G. FALDINI and A. M. GIANELLI (*Chir. d. Org. di Movimento*, 1932, Fasc. 3, p. 249) record observations on 199 cases of fracture of the vertebral column treated at the Rizzoli Institute, Bologna, from 1899 to December 31st, 1929, inclusive. Of the patients, 150 (75.37 per cent.) were males, and 49 (36.62 per cent.) females ; 109 (54.77 per cent.) occurred in the third and fourth decennia. In the causation of cervical and lumbar lesions there was a predominance of indirect violence, and in dorsal lesions of direct violence. Fracture of a single vertebra was the rule, being found in 129 out of 177 in which a radiological examination was made. The twelfth dorsal (twenty-one cases) and the first lumbar (forty-one cases) were the vertebrae most frequently affected. Pain and rigidity were present in 100 per cent., and deformity in 130 out of 187 cases (69.51 per cent.), kyphosis being found in 106 (56.58 per cent.) and scoliosis in twenty-four (12.83 per cent.). Among 184 cases ninety-nine (53.73 per cent.) showed no nervous symptoms, fifty (27.10 per cent.) were paraplegic, and thirty-five (19 per cent.) had a localized sensory or motor paralysis. Paraplegia was most common in fractures of the dorsal vertebrae, being present in thirty-four out of sixty-three cases. In the dorsal region the highest number of paraplegias resulted from fracture of the fifth, sixth, or seventh vertebra. Of seventy-two cases of immediate flaccid paraplegia, six became spastic, in twenty the paralysis became localized, five patients recovered, and forty-one remained unchanged. Of five patients with spastic paralysis, only two recovered, and of twenty-three with localized paralysis only eight. The best results were produced by immobilization. No benefit was derived from laminectomy, even when it was performed early.

Therapeutics

43 Antitoxin Therapy of Erysipelas

D. SYMMERS and K. M. LEWIS (*Journ. Amer. Med. Assoc.*, September 24th, 1932, p. 1082) employ for the treatment of erysipelas an antitoxin prepared by immunizing horses with eight strains of the streptococcus of erysipelas. They consider this a definite advance in the treatment of the disease, but add that it only controls the immediate process, and does not prevent further attacks or cause immunization. The average duration of the disease is reduced by about 60 per cent. and the number of deaths in a series of more than 3,500 patients by 30 per cent. About five out of every hundred patients prove resistant to this method of treatment ; the authors attribute this to the fact that the causative organism is one of many strains. The facial type of erysipelas is more amenable to serotherapy than the body type. Delay in administering the antitoxin at the onset of the complaint and failure to repeat the dose at frequent intervals are two additional reasons for not obtaining good results. Local applications are useless as measures of control, but boric acid and other solutions may increase the comfort of the patient.

44 Bacteriophage Treatment of Staphylococcal Meningitis

R. A. SCHLESS (*Amer. Journ. Dis. Child.*, October, 1932, p. 813), who records an illustrative case, suggests the following classification of staphylococcal meningitis. (1) Localized abscess involving the meninges, and caused by the extension of suppuration from contiguous structures. Such cases can be cured by operation. (2) Meningitis occurring in the course of general staphylococcal septicaemia, the prognosis being invariably fatal. (3) Meningitis of haematogenous origin, most frequently secondary to staphylococcal infection in non-contiguous parts of the body. No recovery has been reported in such cases. (4) Exceedingly mild meningitis, of which one case only was reported, by Lamb in 1928, with recovery following the use of gentian violet. Schless's patient was a boy, aged 13, who developed meningitis following a boil on the back. No improvement followed the intrathecal and intramuscular injection of anti-meningococcal serum, but after cultures of the blood and cerebro-spinal fluid had shown *Staphylococcus aureus*, 5 c.cm. of a *Staphylococcus aureus* bacteriophage was injected intrathecally. Rapid improvement and recovery ensued. This is said to be the first case on record of the intraspinal injection of bacteriophage.

45 Milk Administration in Infantile Disorders

C. G. KERLEY (*Med. Journ. and Record*, November 2nd, 1932, p. 371) considers that by reason of its composition and physical properties cows' milk is readily adapted to the digestive capacities and requirements of infants. Fresh "certified" cows' milk, evaporated milk, and powdered milk are all useful, and the choice must be determined by circumstance. For normal infants Kerley prescribes fresh cows' milk with sugar, starch, and water, an attempt being made to imitate the composition of human milk. The average baby thrives on a mixture containing 3 per cent. fat, 2 per cent. protein, and 7 per cent. carbohydrate, lactose and starch being added in order to raise the carbohydrate content. Healthy infants require 60 to 80 calories per pound of body weight. They should be fed every four hours (for the first month or two). The milk is heated with water and starch for thirty minutes in a double boiler ; this destroys bacteria and renders the milk more readily digestible. Orange or tomato juice is used in every case. The author recommends cod-liver oil, but disapproves of green vegetables in the first few months. Children who have congenital difficulty in assimilating artificial foods, and those whose digestion has been deranged by unsuitable food, require complete physical examination. Some have pyloric stenosis, elongation of the colon and sigmoid, or sphincter

ani spasm. Chronic otitis media and mastoid disease explain some cases, and mucous gastritis, pyloric spasm, intestinal stasis, and chronic colitis are frequently present. Until such disorders have been corrected a maintenance diet is necessary, an evaporated preparation or one of the dried milks being used. Gastric lavage is employed freely in anorexia, vomiting, and mucous gastritis. Atropine is described as being particularly useful in vomiting and colic. Later, evaporated milk is best for children whose digestion has been deranged seriously. Cod-liver oil and orange and tomato juice must be added cautiously since relapses may occur. In these cases one should be content for a few weeks with only a small increase in weight.

Ophthalmology

46 Reading with Closed Eyes

A. H. PIRIE (*Canadian Med. Assoc. Journ.*, November, 1932, p. 488) describes a method of using *x* rays to stimulate the retina and so render possible vision with the eyelids closed. After remaining in total darkness for ten minutes the observer sees light when *x* rays impinge on the retina, and after fifteen minutes can read lead letters; after twenty minutes in the dark he can see properly prepared pictures, and no lens in the eye is necessary. Lead letters for such reading can be arranged on a ribbon in sentences, and an illustration, not larger than one square centimetre, be pricked on a lead sheet. Further applications of this procedure are described. A metallic foreign body inside the eye can be seen and located by the patient; it can cast only one shadow on the retina, and is visualized as single. If lying outside the eye it may cast only one shadow, but if seen as double proof is established of its external localization. Damage to the retina by a metallic foreign body can be recognized, and its position be defined by the use of a grid; if it lies over the blind spot, however, the patient will not be able to see it unless weak *x* rays are employed. The field of vision can be mapped out even in cases of complete cataract and opaque cornea. Pirie thinks it probable that patients suffering from night blindness will not be able to use this method, but this has not been tested yet; neurological cases should be benefited, however. The fact that glass fluoresces under *x*-ray bombardment will enable the ophthalmologist to detect a fragment of it in the eye, even though it is too small to be detected on a photographic film. Stereoscopic vision with closed eyes is described.

47 Emergency Treatment of Ocular Injuries

H. W. GRANT (*Minnesota Med.*, November, 1932, p. 771) emphasizes the importance of making a most careful examination of the eye in any case of suspected injury in view of the serious sequels which may result from inadequate primary treatment. Even with the external parts uninjured complications such as haemorrhage, iridocyclitis, retinal or choroidal tears, and retinal detachment may be present. For the examination the illumination must be fully adequate, and the magnification must be such as to render visible the smallest foreign bodies or wounds. The corneal microscope will frequently afford valuable information which is unobtainable otherwise. Embedded metallic fragments may give rise to oxidized bases which leave a brown stain when the particle is extracted. This stain, if not dealt with, delays convalescence and may interfere with vision; its removal is best effected by a sharp foreign body spud or the dental burr. Cauterization after removal prevents infection and stimulates healing. For burns due to caustic alkalis the United States Pharmacopoeal preparation glycerite of tannic acid is commended; this stops the destructive action of the corrosive and prevents opacity developments in the cornea. Grant has found that relief from pain is more quickly obtained by anaesthetic ointments than by aqueous solutions. In perforating injuries the wound should be closed by means of a conjunctival flap, after the excision of the prolapsed iris, if necessary. Intraocular foreign bodies present serious problems which require considerable experience and *x*-ray localization before removal is attempted. Pre-existing infections complicate any ocular injuries, especially when the infection is endogenous, as in syphilis or tuberculosis. After severe injuries with infection and in traumatic inflammation non-specific protein therapy is useful; the author prefers small intravenous doses of typhoid vaccine to milk injections. Large doses of sodium salicylate—approximately 1 grain for each pound of body weight, and administered in a starch retention enema—have proved most beneficial in aged patients and others in whose case vaccine injection is contraindicated.

48 Vernal Conjunctivitis

L. LEHRFELD (*Arch. of Ophthalmol.*, September, 1932, p. 380) points out the many distinctions between the limbal and palpebral types of vernal conjunctivitis. The former is the more benign in symptoms and course, never progressing to the cobblestone palpebral type. Having used intradermal tests, he considers the condition to be an allergy from street dust, animal dust, or pollen. Itching, a ropy discharge, and the presence of eosinophils in the discharge and blood are distinctive. The differential diagnosis has to be made from acute catarrhal conjunctivitis, "pink eye," and trachoma. Radium and calcium gluconate have only a limited value in treatment, the best results being obtained from the application of boric lotion seven times a day, with the addition of phenacaine lotion in severe cases. This treatment alleviates the symptoms till a natural desensitization occurs.

Obstetrics and Gynaecology

49 Fibroids and Cardiovascular Changes

G. V. TACCANI (*Ann. di Ostet. e Ginecol.*, October 31st, 1932, p. 1371) records his observations on the cardiovascular changes in forty-two women aged from 31 to 57 who had been operated on for fibroids in the Mangiagalli Clinic at Milan during 1930, and comes to the following conclusions. Before the operation the patients showed a rise of the maximum blood pressure, diminution of the haemoglobin and colour index, and a spasm of the capillaries; whereas after the operation there was a return to normal conditions. Taccani suggests that the cardiovascular changes found in patients suffering from fibroids, independently of metrorrhagia to which they are often subject, are to be attributed to a dysfunction of the endocrine system, of which the anatomical substratum is to be found mainly in the lesions of the ovary and thyroid.

50 Glycosuria in Pregnancy

R. RICHARDSON and RUTH S. BITTER (*Amer. Journ. Obstet. and Gynecol.*, September, 1932, p. 362) discuss the occurrence of glycosuria in pregnancy and record the results of their investigations. A sugar tolerance test was performed on each of 247 women presenting themselves for pre-natal care: the usual technique was adopted for the test, and 1.75 grams of dextrose per kilogram of body weight was administered in each case. Specimens of urine for examination were obtained before the sugar was given and at the time of the taking of the last blood sugar—that is, two hours after the time of the administration of the glucose. It was found that 60 per cent. of the series showed no gross abnormalities of the sugar metabolism; 20 per cent. had obvious sugar in the urine, without any abnormality of the blood sugar curve. No definite variation was determinable in the different periods of pregnancy, and no difference was found between primiparae and multiparae in excreting sugar: 8 per cent. showed a blood sugar curve on which a diagnosis of lowered carbohydrate tolerance would usually be made. The authors also submit evidence that 90 per cent. of women during pregnancy show microscopic traces of

glucose in the urine, and that on the twelfth day of the puerperium only 42 per cent. still have glucose in the urine in microscopic quantity. It is suggested that this may be due to damage to the renal tubules which occurs in pregnancy.

51 Polyneuritis due to Apiol

Apiol, an extract from parsley seed, was first employed as an antipyretic, but more recently as an efficient abortifacient. SCHACHTER (*Gynécol. et Obstét.*, October, 1932, p. 337) records animal experiments and clinical observations which show that polyneuritis frequently follows its administration. This is caused by tri-ortho-cresyl phosphoric acid, the toxicity of which is due to its marked neurotropism. Apiol contains 28 to 50 per cent. of this compound. A latent or incubation period of ten to fifteen days elapses after the administration of the drug. Then the first symptoms (gastralgia, gastro-enteritis) of intoxication appear, together with a progressive weakness of the lower extremities, which renders walking difficult. Formication and diffuse pains accompany this weakness. Paralysis, first of the lower, with subsequent involvement of the upper, limbs then supervenes. Only the peripheral parts are attacked ; in all cases a total paresis of the legs, feet, and hands is present with muscular hypotony and atrophy. Of the hands, the right is especially affected ; the thenar and hypothenar eminences and interosseous muscles are markedly atrophied. The Achilles reflex is abolished, but the patellar and osteo-tendinous reflexes are normal. Sensation (superficial and deep) is unaffected. The condition, which has been noted only in females, is then of a motor type with special localization in the periphery of the extremities and constant absence of sensory involvement. No effective treatment is known and the prognosis is bad, most cases ending in grave invalidism ; therefore Schachter maintains that the sale and administration of apiol should be rigorously supervised.

Pathology

52 Destruction of Treponema pallidum by Pyrexia

RUTH A. BOAK, C. M. CARPENTER, and S. L. WARREN (*Journ. Exper. Med.*, November, 1932, p. 725) have conducted an investigation of fever temperatures on the growth and fertility of rabbits. In the production of pyrexia use was made of the short-wave vacuum tube radio-oscillator. The experimental animals were exposed in a wooden box to the electrostatic field of two high-frequency oscillators in a Hartley circuit. The D.C. plate voltage on the oscillating tubes ranged from 1,800 to 2,000 volts, and the plate current from 2 to 4 milliamperes. The high-frequency waves oscillated between two aluminium plates on opposite sides of the box, producing an electrostatic field in which the animals were heated. It was found that the repeated elevation of body temperatures of male and female rabbits to 41° and 42° C. from two to five times per week by short radio waves (30 m.), beginning from 29 to 171 days of age and extending through their first period of gestation, failed to injure their growth or to interfere with mating, fertilization, or the development of the young *in utero*. Having shown that fever induced by this means had no obvious detrimental effect on the physiological activities of normal rabbits, the authors (ibid., p. 741) determined to ascertain the thermal death time of *Treponema pallidum*. This was carried out by exposing saline suspensions of infected rabbit testicle to temperatures of 37.5° to 42° C. in a specially constructed and carefully controlled series of water baths, described in the same journal by F. W. BISHOP, C. M. CARPENTER, and S. L. WARREN (ibid., p. 719). The results showed that the organism was killed in five hours at 39° C., in three hours at 40° C., in two hours at 41° C., and in one hour at 41.5° C., as determined by non-infectivity to rabbits. Finally, C. M. CARPENTER, RUTH A. BOAK, and S. L. WARREN (ibid., p. 751) exposed rabbits that had been experimentally infected with human syphilis by testicular inoculation to high-frequency radiation so as to produce pyrexia of a degree sufficient to prove lethal to *Treponema pallidum*. At varying times after inoculation rabbits were exposed in a high-frequency electrostatic field (10,000 kilocycles), either one long exposure or multiple short ones being given. It was found that twenty to thirty short pyrexias of 41° to 42° C. completely destroyed the spirochaetes, so that healing of the lesions occurred and subinoculation of the infected tissues into normal rabbits proved harmless. A similar result was attained by a single exposure of six hours to a temperature of 41.5° to 42° C. The fever treatment proved effective at any stage of experimental syphilis in rabbits.

53 Incidence of Punctate Basophilia

W. T. NELSON, L. LOCKWOOD, and KATE MACKEY (*Med. Journ. of Australia*, September 10th, 1932, p. 317) report an investigation into the incidence of punctate basophilia. The authors' results do not agree with those of various other workers in the same field, but a different technique was employed. It is emphasized that in demonstrating this condition it is necessary to prepare the films while still fresh, to use a suitable stain (such as an alkaline methylene blue solution) and, finally, in searching the films, to use a dark field technique. Estimations of stippled cells were made upon blood films from groups of workers: 255 men with no history of exposure to lead had an average of 937 stippled cells per million red cells ; fifty-nine men with a history of very slight exposure to lead had an average of 4,335 stippled cells per million ; and forty-one men with a severe lead occupational hazard had an average of 14,220 stippled cells per million. Twelve men in this last group suffering from lead poisoning had an average of 36,382 stippled cells per million red cells. It is shown that as the lead hazard becomes greater the percentage of persons with high stippled cell counts increases. There appeared to be no difference between the appearance of the stippled cells found in blood films from cases of lead poisoning and those found in normal controls. The patients with lead poisoning had, on an average, thirty-eight times as many stippled cells as the normal controls and sixty-nine times as many cells of the coarsely stippled variety. Smokers, as a class, were not found to differ from non-smokers in regard to the numbers of stippled cells. The importance of considering all possible causes of high stippled cell counts is illustrated by the fact that in a case of pernicious anaemia there were 20,000 stippled cells per million erythrocytes.

54 Standardization of Anti-gas-gangrene Serums

M. WEINBERG, J. DAVESNE, and A. R. PRÉVOT (*Ann. de l'Inst. Pasteur*, October, 1932, p. 387) report on the methods that they have found most successful in the standardization of serums for use against gas gangrene. Previous work has convinced the authors that for such serums to be effective they should contain both antibacterial and antitoxic properties. Anti-*welchii* serum, standardized by intramuscular injection of a guinea-pig with one or two lethal doses of a culture of *Cl. welchii*, so as to determine its anti-bacterial power, ought to contain at least 100 units. The same titre should be expected if it is titrated on the mouse so as to determine its antitoxic power. Serum against *Cl. septique* may be titrated for its antitoxic power by intravenous injection into the rabbit. A satisfactory serum should contain 1,000 units of antitoxin. The same serum, when titrated on the mouse, is found to contain only about 250 antitoxic units per c.cm. The same relations hold true with serum prepared against *Cl. histolyticum*. Serum against *Cl. oedematiens* may be titrated by the Ehrlich method, inoculating 100 minimal lethal doses of toxin subcutaneously. Such a serum should have 1,000 units of antitoxin per c.cm. The authors point out the advantages of using the mouse as the animal of choice for the standardization of serums towards the gas-gangrene organisms, and are convinced that the results obtained are capable of a high degree of precision.

WE MODERNS PREFER

electric lights to old oil lamps

and motor cars to the

horse and gig of an earlier

age because we get results

more quickly and more efficiently.

Similarly in constipation — a modern day has developed a modern way — AGAROL. To meet every modern need, this product combines efficiency with palatability. No oily taste, no artificial flavouring to get used to.

AGAROL Brand Compound is the original mineral oil and agar-agar emulsion with phenolphthalein. It softens the intestinal contents and gently stimulates peristalsis.

Effectiveness must be experienced. A supply gladly sent for trial.

AGAROL *for Constipation*

BRAND COMPOUND

WM. R. WARNER & CO., LTD., *Manufacturing Chemists,*

300, Gray's Inn Road, London, W.C.1.

Sphagnol for Haemorrhoids

"I am constantly prescribing it"

Haemorrhoids are very painful, so that any healing ointment used should also be soothing and cooling. Sphagnol Peat Ointment is most suitable, and many doctors have found it excellent as a palliative. The letter quoted above, for instance, reads in part: "I have found Sphagnol Ointment of the greatest value again and again in cases of haemorrhoids, including haemorrhoids in pregnancy. Nothing in my experience has proved so effective, apart from surgical interference, and I am constantly prescribing it."

—M.B., M.R.C.S.

The peat distillate principle contained in Sphagnol Ointment is present to a lesser degree in Sphagnol Shaving Soap. There is probably no other shaving soap that leaves the skin so cool and fresh. Use it yourself. Write to us at the address below and we will send you free samples of our preparations.

Peat Products (Sphagnol) Ltd., Dept. B 95, 21, Bush Lane, London, E.C.4.

Valentine's Meat-Juice

FOR Quieting the Irritable Stomach and Aiding the Tired Digestive Organs, for Refreshing the Fever Patient and for Restoring and Strengthening when Other Food Fails, Valentine's Meat-Juice is used in Hospitals and prescribed by many leading Physicians and Surgeons.

Physicians are invited to send for Clinical Reports from Hospitals and General Practitioners in all parts of the world.

For sale by European and American Chemists and Druggists.

Valentine's Meat-Juice Co., Richmond, Vir., U.S.A.

JB 94

"STERULES" Regd.

FOR HYPODERMIC, INTRAMUSCULAR AND INTRAVENOUS USE AND FOR INHALATION.

AMYL NITRITE "STERULES" are used in Angina Pectoris, and threatened fainting and collapse, with success.

The Surgeon's Guarantee *with* London Hospital Catgut

These vital factors constitute the Surgeons Guarantee with London Hospital Catgut.

I Absolute conformity with the conditions justly demanded by the Therapeutic Substances Regulations. 1931. assures sterility.

II The highest possible percentage of sterility is being obtained under the tests prescribed by The Therapeutic Substances Regulations

III The lamb intestines are from Animals reared on Virgin land, reducing to a minimum all tendencies to Tetanus.

IV Every Animal is certified and subjected to ante and post-mortem examination.

V Elasticity and Tensile strength are constant.

VI Absorbability is dependable.

VII During treatment ligatures are subjected to 25 major processes.

VIII Aseptic control commences at the abattoir and prevails throughout the entire process.

U.G.B Washed & Sterilised MEDICAL BOTTLES

MODERN annealing ovens deliver bottles bright and sterile. Packed without special treatment a film will gradually appear on the surface of the glass. Hence the necessity of our scientific sterilising process passing bottles through boiling distilled water and drying in super-heated filtered air before packing in dust-proof cartons. How vastly superior to many competitive makes of so-called "washed and papered" bottles which are generally only rinsed in none too clean ordinary water.

OUR SALES OF THIS UNIQUE SERVICE STEADILY INCREASE YEAR BY YEAR.

ANNOUNCEMENT

In addition to the white enamelled Aluminium Screw-Cap service the full range of sizes complete with an attractive design of BLACK KORKALITE MOULDED CAP will shortly be available.

NEW APPLICATION OF NATURAL PRINCIPLE

The essential and basic principle of the "E.M.C." (En Mains Croisées) is the old but very natural one of two hands crossed with the fingers interlocked. The hands hold. The fingers, pliable and mobile, mould and lift. There is maximum support, minimum compression . . . pressure is graduated and oblique, from lower front to upper back . . . and pressure is easily adjustable.

When this principle is applied in a corset belt, the importance of the "E.M.C." becomes at once apparent. Its advantage in general abdominal ptosis, tuberculosis cough, and in all cases where abdominal muscles are subjected to strain is clearly indicated.

The opinions of eminent consultants support our own view, which is that every practising doctor and surgeon should be aware of the remarkable features of this appliance. For this purpose we have prepared a brochure which illustrates (with prices) the application of the Crossed Hands principle in a number of corset belts suitable for patients under various conditions. A copy will be sent on request.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON.

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or who wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,

SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 59.

Telephone: 157 Basingstoke.

RUTHIN CASTLE, NORTH WALES

REDUCTION OF FEES

In view of the present economic position, the inclusive fees at Ruthin Castle, formerly from 17 guineas a week, have been reduced to from 15 guineas a week.

The fees include medical attendance, all scientific investigations that may be needed, such as analyses, bacteriological cultures, the ordinary x-ray examinations, and electrocardiograph readings; all treatment that may be prescribed, such as special diets, insulin, artificial sunlight, electrical treatment, baths, massage, nursing; medicines or vaccines, board, and lodging.

The only extra charge is that for a complete alimentary x-ray examination, or for x-ray therapy.

Many people who would go abroad for health will not do so this winter. All the usual forms of treatment are given at Ruthin Castle. The climate is mild. The annual rainfall is 30.5 inches, that is, less than the average for England. There is central heating throughout. Should the accommodation in the Castle not prove sufficient, comfortable rooms can be obtained near by for those undergoing treatment.

Address—THE SECRETARY, Ruthin Castle, North Wales. Telegrams: CASTLE, RUTHIN. Telephone: RUTHIN 66.

Salary at usual L.C.C. rates.

Applicants are required to state name, address, age, qualifications, and experience, and to send to the Hon. Secretary at the above address not later than January 26th.

No testimonials are required unless asked for.

The final selection will be made by the L.C.C., and the successful candidates only will be communicated with.

LONDON COUNTY COUNCIL.

Applications invited from registered Medical Practitioners for appointment as HOUSE PHYSICIAN at LEWISHAM HOSPITAL, High Street, Lewisham, S.E.13. Position recognized for requirements of M.D.London. Salary £80 a year, together with board, lodging, and laundry, subject to temporary reduction. Appointment is for six months in the first instance, but may be extended for a further period of six months. Duties are assigned by the Medical Superintendent and include, if necessary, assistance at other establishments under the control of the Council.

Forms of application obtainable (stamped addressed foolscap envelope necessary) from Medical Officer of Health (Staff Division 3a), County Hall, Westminster Bridge, S.E.1, returnable by January 27th. Canvassing disqualifies. Further inquiries should be addressed to Medical Superintendent at the hospital.

ROTHERHAM HOSPITAL.

Wanted, CASUALTY HOUSE SURGEON (male). Qualified. Salary £150, with board, residence, and laundry. 130 Beds.

Applications, with copies of recent testimonials, etc. to be sent to the Secretary, G. W. ROBERTS, 8, Moorgate Street, Rotherham.

CITY OF MANCHESTER.

PUBLIC HEALTH DEPARTMENT.

CRUMPSALL HOSPITAL AND INSTITUTION.

APPOINTMENT OF AN ASSISTANT MEDICAL OFFICER.

The Public Health Committee invites applications from qualified Medical Men for the position of Assistant Medical Officer at the Crumpsall Hospital (1,568 beds) and Institution (2,000 beds), including 600 beds for Mental Patients, Crescent Road, Crumpsall, Manchester.

Every applicant must be a registered Medical Practitioner and unmarried.

Preference will be given to applicants with previous Hospital experience.

The Hospital is a recognised Training School for nurses and is equipped with all modern Hospital requirements.

Salary £275 per annum, subject to a temporary deduction of £7 10s. per annum. The amount payable is, therefore, £267 10s. per annum, with board, residence, and laundry in addition, subject to the terms and conditions of the Manchester Corporation Grading Scheme.

No bonus.

The appointment will be made, in the first instance, for a period of six months. The successful candidate, however, will be eligible for re-appointment for a further period of six months at the end of that period.

Applications, stating fully the age, training, qualifications, and experience of the candidate, with copies of three recent testimonials, and endorsed on the envelope "Assistant Medical Officer, Crumpsall Hospital," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must be received by him not later than Saturday, January 28th.

The candidate appointed will be required to commence duty on March 1st, to devote the whole of his time to the duties of the position, to pass a medical examination, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

Town Hall, F. E. WARBRECK HOWELL,
Manchester. Town Clerk.
January 16th, 1933.

MINISTRY OF HEALTH.

The Minister of Health invites applications for a VACANT APPOINTMENT on the medical staff of the Ministry. The salary commences at £833 per annum, and rises by twelve annual increments to a maximum of £1,146 per annum. This scale of remuneration is liable to review.

The appointment will carry the usual Civil Service conditions as to pension, holidays, etc., and the officer will be required to devote his whole time to the public service and must be prepared to work in any part of England or Wales if required to do so.

Candidates must possess a University degree in Science with special knowledge and experience of biochemistry and physiology in relation to food and nutrition. They must conform to the Civil Service Nationality rule.

Canvassing through Members of Parliament or in other ways will render a candidate liable to disqualification.

Forms of application, with further particulars of the appointment, may be obtained from the Director of Establishments, Ministry of Health, Whitehall, S.W.

No application can be considered unless received on the prescribed form not later than February 13th.

CITY OF BIRMINGHAM.

SELLY OAK HOSPITAL. (500 Beds.)

CASUALTY OFFICER (Male).

Applications are invited from fully qualified Medical Practitioners for whole-time appointment as Casualty Officer (male) at the Selly Oak Hospital Birmingham. The appointment will be for a period of six months, in the first instance, but may be extended at the end of that time for a further period of not exceeding six months.

Salary at the rate of £200 per annum, and full residential emoluments. The salary and emoluments will be subject to any "voluntary abatement" in force from time to time. The officer appointed will be required to refund to the Council all fees, allowances, and emoluments (other than the foregoing) received by him.

Further particulars may be obtained from the Medical Superintendent at Selly Oak Hospital, to whom applications, stating age, experience, and qualifications, with copies of recent testimonials, should be forwarded not later than Wednesday, February 8th.

F. H. C. WILTSHIRE, Town Clerk.
The Council House, Birmingham.
January, 1933.

DERBYSHIRE EDUCATION COMMITTEE.

ASSISTANT SCHOOL MEDICAL OFFICER (Male).

The Derbyshire Education Committee require the services of an Assistant School Medical Officer (male) at a salary of £500, rising by annual increments of £25 to £700 per annum, subject to a temporary economy reduction, together with reasonable travelling expenses.

Candidates must be registered Medical Practitioners of at least three years' standing.

Experience in this work, the administration of anæsthetics, and Mental Deficiency is desirable.

The appointment will be a designated post under the Local Government and Other Officers Superannuation Act, and the successful candidate will be required to pass a medical examination.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office, and will act under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before Thursday, January 26th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months notice on either side.
